INDEX

NAME INDEX

Abbot (Dr. C. G.), Periodicities in Solar Variation reflected in Weather, 564; Utilization of Sun Power, 744
Abraham (Dr. E. P.), and Dr. E. Chain, An Enzyme from Bacteria able to Destroy Penicillin, 837
Adam (Dr. L.), Primitive Art: Past and Future, 519
Adam (M. G.), Variation of Faint Fraunhofer Lines, 780
Adam (Prof. N. K.), Water and All its Properties (*Review*), 145
Adams (R.), and L. J. Dankert, Restricted Rotation in Arylamines, 690
Adams (S. C.), [G. N. Tyson and], Configurations of Quadricovalent Complexes, 103
Adamson (A. M.), New Termite Intercastes, 655
Adler (Dr. J.), [Dr. J. M. Robson and], Site of Action of Œstrogens, 60
Aitken (Dr. A. C.), Probability and Relative Frequency (*Review*), 114; Determinants and Matrices (*Review*), 665
Alexander (A. E.), Pearl Formed Around a Rotifer, 370
Alexander (Prof. W. P.), awarded the Cornelius Amory Pugsley medal of the Buffalo Museum of Science, 161
Allen (C. W.), Spectrum of bright Chromospheric Eruptions, 749
Allen (Prof. H. S.), The Search for Truth, 637; Dr. F. L. Arnot, 832
Allen (H. W.), J. K. Holloway and G. J. Haeussler, Parasites of the Oriental Fruit Moth, 719
Allen (W.), [R. Fitzmaurice and], Sound Transmission in Buildings: Practical Notes for Architects and Builders (*Review*), 417
Alter (G.), A Photographic Survey of Galactic Clusters, 69
Alvarez (Dr. J. G.), Health Conditions in Venezuela, 836
Amery (L. S.), Indian Art and Religion, 680
Ananthapadmanabhan (T. S.), [Prof. K. S. Krishnan, S. L. Chorghade and], Dimorphism of Diphenyl Octatetraene Crystals, 333
Anderson (C. A.), Crystallization of Olivine-basalt, 236
Anderson (E. G.), and R. A. Brink, Cytogenetics of Maize, 270
Anderson (Prof. E. H.), and Prof. G. T. Schwenning, The Science of Productive Organization (*Review*), 574
Anderson (H. V.), [J. S. Long and], Chemical Calculations. Fourth Edition (*Review*), 545
Angström and Jacobson, Temperature Measurements in Vänern and Götaälv, 749
Appleton (Prof. E. V.), Sir J. J. Thomson, 353
Arakawa (Dr. H.), [Dr. Y. Nishina, Y. Sekido, H. Simamura and], Cosmic Ray Intensities in relation to Cyclones and Anticyclones, 95
Arber (Dr. Agnes), An Aztec Herbal, 81
Arber (Muriel A.), Outline of South-West England in relation to Wave-attack, 27
Archenhold (G. H. A.), Distribution of Sunspots over the Sun's Disk, 780
Arctowski (H.), Solar Faculæ and Solar Constant Variations, 495
Argand (Prof. E.), [death], 740
Argument (C.), [C. W. Gibby and], Adsorption at a Liquid Interface, 203
Arkhangelsky (Prof. A. D.), [obituary article], 395
Armstrong (Dr. E. F.), Progress in Biochemistry (*Review*), 383; Hydrocarbons (Review), 507; The Science of Plant Protection (*Review*), 569; History of Laboratory Apparatus (*Review*), 604
Arnold [Kerr, Shannon and], Vibration of Propeller Blades, 843
Arnot (Dr. F. L.), [obituary article], 832
Aronson (Dr. J. D.), Disease among Natives of Alaska, 298
Arrowsmith and Wolfe, Use of Refrigeration to Delay Age-hardening, 495
Arthur (Prof. A.), Lecture Demonstrations in General Chemistry (*Review*), 666
Ashcraft (G.), Barnacles attached to Birds, 561
Ashworth (late Prof. J. H.), Bronze memorial plaque to, 161
Aslin (Miss), Library Catalogue of Printed Books and Pamphlets on Agriculture published between 1471 and 1840. Second edition, 92
Astbury (Dr. W. T.), Florence O. Bell and C. S. Hanes, X-Ray comparison of Natural and Synthetic Starch, 558
Aston (Dr. F. W.), Sir J. J. Thomson, 355
Atkinson (R. d'E.), Accretion and Stellar Energy, 271
Austen (A. E. W.), and S. Whitehead, Electric Strength of Some Solid Dielectrics, 595
Austin (R. G.), Aids to Physical Chemistry (*Review*), 544

Babcock (E. B.), [G. L. Stebbins and], Apomixis in Crepis, 34
Bacharach (A. L.), Vitamin-free Diets for Animal Experiments, 28; [J. Madinaveitia, Prof. J. A. Todd, M. R. A. Chance and], Mucolytic Activity of Diffusing Factor Preparations, 197
Bagshawe (T. Wyatt), Two Men in the Antarctic: an Expedition to Graham Land, 1920–1922 (*Review*), 282
Bailey (Dr. E. B.), Submarine Canyons, 493
Baillie (Sir James), [obituary article], 54; bequest to Leeds University, 617
Baker (A. H.), and S. R. Finn, Hydration of Carbon Dioxide and its Influence on Germicidal Activity of Hypochlorite Aerosols, 747
Baker (H. H.), [death], 678
Baker (T. Thorne), Electrical Photo-Engraving, 372
Baldacci (Prof. E.), Taxonomy of the Actinomycetes, 170
Baldwin (Dr. E.), [D. J. Bell and], *l*-Galactose as a component of a Polysaccharide of Animal Origin, 559
Balfe (M. P.), M. Irwin and Dr. J. Kenyon, Complex Rotatory Dispersion of Optically Active Tetrahydrofuryl-2-carbinol, 686
Bamford (late F.), Poisons: their Isolation and Identification (*Review*), 414
Banta (A. M.), [H. H. Durham and], Colchicine Treatment of Daphnia, 170
Barber (H. N.), and J. R. Price, Nature of the Feulgen Reaction with Nucleic Acid, 335; 808
Barnard (S.), and J. M. Child, Advanced Algebra (*Review*), 665
Barnell (H. R.), Ripening of the Banana, 494
Barry (V. C.), and Prof. T. Dillon, Occurrence of Xylans in Marine Algæ, 620
Bassett (M. J.), Attainment of Very High Pressures, 103
Baughan (E. C.), Resonance in the Chloracetic Acids, 461; and Prof. M. Polanyi, Energy of Aliphatic Carbon Links, 685
Bawden (F. C.), appointed head of the Department of Plant Pathology at Rothamsted Experimental Station; work of, 331
Baxter and Titus; and Lundstedt, Atomic Weight of Iodine, 405
Bayliss (E. P.), Map of Antarctica, 22
Bayon (Dr. H. P.), The School of Salerno, 57
Beadle (L. C.), and J. B. Cragg, Osmotic Regulation in Freshwater Animals, 588
Beale (G. H.), Genetics of Verbena, 495; J. R. Price and R. Scott-Moncrieff, Biochemistry of Flower Pigments in Verbena, 690

Beard (J. R.), Electrical Engineers and the War, 615; Planning the Post-War World, 692
Beauchamp (R. S. A.), Chemistry and Hydrography of Lakes Tanganyika and Nyasa, 253
Bedford (Duke of), [death], 295; [obituary article], 394
Beeson (C. F. C.), and N. C. Chatterjee, Biological Control of *Lantana aculeata*, 809
Beevers (Dr. C. A.), and W. Hughes, Crystal Structure of Rochelle Salt, 96
Begon (Dr. L.), Murder by Children and Adolescents, 456
Beharrel (J.), Kitchen Waste for Feeding Farm Stock, 47
Bejarano (Dr. J.), Diet and Nutrition in Colombia, 338
Belcher (R.), and R. V. Wheeler, Composition of Coal, 525
Bell (A. E.), Christian Huygens, 1629–1695, 511
Bell (Dr. D. J.), Introduction to Carbohydrate Biochemistry (*Review*), 545
Bell (D. J.), and Dr. E. Baldwin, *l*-Galactose as a component of a Polysaccharide of Animal Origin, 559
Bell (Florence O.), [Dr. W. T. Astbury, C. S. Hanes and], X-Ray comparison of Natural and Synthetic Starch, 558
Bell (Prof. H. P.), Core Disease in the Apple, 34
Bell (R. P.), Resonance in the Chloracetic Acids, 166
Bellamy (D.), Heating Private Air Raid Shelters, 517
Bellerby (Prof. J. R.), awarded a Leverhulme research fellowship, 93
Bendall (F. W. D.), appointed adviser in educational matters to Service men and women, 396
Beneš (Dr.), Czech Culture under German Rule, 126
Bennett (C. V.), [death], 740
Bennett (Dr. H. H.), Soil Conservation (*Review*), 415
Benson (Prof. W. N.), [R. A. Keble and], Graptolites of Australia, 561
Bent (A. C.), More Life-histories of North American Birds, 689
Beresford (J. B.), [death], 553
Bergmann (Dr. E.), [Prof. C. Weizmann, Prof. V. Henri and], Identification and Determination of Aromatic Compounds in Mineral Oils, 230
Bernal (Prof. J. D.), M. V. Lomonosov (1711–1765), 16
Bersu (G.), Excavation at Little Woodbury, Wilts: The Settlement as Revealed by Excavation, 841
Bertram (C.), Arctic and Antarctic: the Technique of Polar Travel (*Review*), 282
Beust (Nora E.), 500 Books for Children, 23
Beveridge (Sir William), appointed commissioner for available resources of man-power, 23
Bhaduri (P. N.), and C. S. Semmens, Advantages of Uranium Fixation in Modern Cytological Technique, 100
Bhatia (Dr. B. L.), The Fauna of British India, including Ceylon and Burma: Protozoa: Sporozoa (*Review*), 384
Bhatia (D.), Peculiar Water Relations of a Diatom, 591
Biancolli (L.), Stereophonic Recordings of Enhanced Music, 174
Bierens de Haan (Dr. J. A.), Die tierischen Instinkte und ihr Umbau durch Erfahrung: eine Einführung in die allgemeine Tierpsychologie (*Review*), 317
Birkenhauer (H.-F.), The Illinois Basin Earthquake of November 23, 1939, 809
Birnbaum (N.), [S. M. Edmonds and], Solubility of Lead Salts, 720
Birnbaum (Dr. H.), Depopulation in France, 427
Bisby (G. R.), and E. W. Mason, Pyrenomycetes recorded for Britain, 748
Bitter (F.), Magnetic Properties of the Transition Elements, 405
Black (R.), [E. W. Sinnott and], Cell-division, 68
Blackett (Prof. P. M. S.), awarded a Royal medal of the Royal Society, 679; work of, 750
Blackie (A.), Visible Sound Waves, 369
Blackman (Prof. A. M.), Recent British Excavations in Egypt (*Review*), 664
Blackwall (Elizabeth), Life-cycle of *Blastocladia Pringsheimii*, 495
Blagden (Dr. J. W.), [death], 833
Blair (Prof. D. M.), Problems of Neurohistology (*Review*), 571
Blake (G. S.), [death], 55
Blakeslee (Dr. A. F.), Induced Evolution through Chromosome Changes, 269
Blüh (Dr. O.), Mixed Radioactive Indicators in Physiological Experiments, 233
Bodio (L.), centenary of the birth of; work of, 488
Boeke (Prof. J.), Problems of Nervous Anatomy (*Review*), 571
Bonn (M. J.), Totalitarian States and the place of Economics in World Affairs, 241
Booth (H. S.), and M. C. Cassidy, Thiophosphoryl Chlorofluorides, 749
Born (Prof. Max), Sir J. J. Thomson, 356
Borsinger (P.), Swiss Short-Wave Emissions, 58
Bosazza (Dr. V. L.), Adsorption of Malachite Green by Clays and Allied Minerals, 334; Occurrence of Vanadium and Molybdenum in Clays, 746
Boswell (Prof. P. G. H.), Geological History and Mineral Resources of South Africa (*Review*), 214
Boswell and Whiting, Respiration in the Higher Plant, 783
Bound (M.), [Dr. G. D. Rochester and], Absorption of Cosmic Ray Protons in Lead, 745
Bounoure (Prof. L.), L'Origine des cellules reproductrices et le problème de la lignée germinale (*Review*), 822
Bourne (Sir Alfred), [death], 88
Bourne (Dr. G.), Nutrition and the War (*Review*), 571
Bourneville (Dr. D. M.), centenary of the birth of; work of, 488
Bowen (Prof. N. L.), Nodal Points on Crystallization Curves of Solid Solutions, 562; Physical Controls in Adjustments of the Earth's Crust, 563
Bower (Sir Percival), Rising Cost of Generating Electricity, 92
Bowie (Dr. W.), [death], 516; [obituary article], 645
Boyd (E.), [Prof. W. D. Harkins, Dr. T. F. Young and], Energy and Entropy of Extension and Spreading of Mobile Monolayers, 406
Boyd (G.), Electric Utilities at the New York World's Fair, 487
Boyes (J. W.), [H. Peto and], Triploid Sugar Beet, 748
Boyle (Dr. R. W.), presented with the Flavelle medal of the Royal Society of Canada, 171
Boys (Sir Charles), Sir Oliver Lodge, 327
Bradford (Dr. S. C.), Information and Progress in Engineering and Industry (*Review*), 7
Bragg (Sir William), Sir J. J. Thomson, 352; The Extra Spots of the Laue Photograph, 509; Science and National Welfare, 731, 741
Bragg (Prof. W. L.), The Physics of Metals (Norman Lockyer lecture), 275; Sir J. J. Thomson, 354
Brandes (Prof. G.), Buschi: Vom Orang-Säugling zum Backenwülster (*Review*), 150
Brasher (W. K.), and B. P. Moss, Supersonic Signal Method for Telephone Calls, 300
Breit (G.), Theory of Nuclear Resonances, 592
Breit (Juanita), [Prof. J. C. Fardon, Rev. G. Brotzge, Sister M. Kenneth Loeffler and], Attraction Fields *in vitro*, 619
Brenchley (Dr. Winifred E.), Woodlands in Agriculture (*Review*), 475
Bretscher (Dr. E.), Radioactivity of Be^{10}, 94; and L. G. Cook, Production of Actinium C'' from Lead, 430
Brewer (Dr. A. K.), [Dr. A. Lasnitzki and], Increase of Heavy Potassium in Plasma, 807
Brewer (Griffith), elected president of the Royal Aeronautical Society; work of, 19
Briggs (Prof. E. A.), Anatomy of the Sheep's Brain: a Laboratory Atlas for Students of Zoology (*Review*), 546
Briggs (R. W.), Tumour Induction in *Rana pipiens* Tadpoles, 29
Brightman (R.), Scientific Organization of Work (*Review*), 284; Preparation of Reports (*Review*), 419
Brink (R. A.), [E. G. Anderson and], Cytogenetics of Maize, 270
Brinton (C.), Social Progress, 742
Britton (E. B.), Insect Fauna of a Hornbill's Nest, 33
Brøgger (A. W.), Development of Norwegian Cultural History, 67

Bromehead (C. E. N.), Cornish Tin Mining, 405
Broom (Dr. R.), Classification of Sub-human Types, 94
Brotzge (Rev. G.), [Prof. J. C. Fardon, Sister M. Kenneth Loeffler, Juanita Breit and], Attraction Fields *in vitro*, 619
Brown (F. G. W.), The Theory of Group Representations (*Review*), 283
Brown (Prof. W.), Plant Disease in relation to the Public (Chadwick lecture), 118
Browne (A. W.), [J. A. Wheat and], Perchlorides of Hydrogen, 434
Brownlea (A.), Drinking Habits of Animals, 522
Broyer (T. C.), [Prof. D. R. Hoagland, P. R. Stout and], Upward Movement of Salt in the Plant, 340
Brückmann (Dr. G.), and Prof. S. G. Zondek, 'Congenital' Copper Deposit in the Rat, 30
Brunauer (S.), and others, Van der Waals Adsorption of Gases, 371
Brunt (Prof. D.), Weather and Weather Prophets (*Review*), 818
Bryant (A.), Unfinished Victory (*Review*), 209
Bryson (V.), [L. C. Dunn, S. Gluechsohn-Schoenheimer and], Genetics of the Tails of Mice, 689
Bucher (Prof. W. H.), Origin of the Submarine Valleys on the Continental Slopes of the North Atlantic, 407
Buckingham (Dr. R. A.), [Prof. H. S. W. Massey and], Collisions of Neutrons with Deuterons and the nature of Nuclear Forces, 776
Buckley (Dr. O. E.), appointed president of the Bell Telephone Laboratories, Inc., 834
Bull (Prof. H. S.), Direct-Current Machinery (*Review*), 668
Bullard (Dr. E. C.), Submarine Geology and Geophysics, 432
Bullen (Dr. K. E.), appointed to the Department of Mathematics in Melbourne University, 458
Burdon (Prof. K. L.), A Textbook of Microbiology. Second edition of "A Textbook of Bacteriology" (*Review*), 149
Burg (A. B.), Methylboric Acid, 690
Burkill (I. H.), [Sir David Prain and], An Account of the genus Dioscorea in the East. Part 2: The Species which Twine to the Right; with Addenda to Part 1, and a Summary (*Review*), 503
Burkitt (M. C.), Stone Age Cilicia, 58
Burlinghame (Dr. C. C.), Psychology in War-time, 712
Burnet (W. C.), [death], 224
Burnham (C. R.), and J. L. Cartledge, Smut Resistance and Interchanges in Maize, 622
Burtt-Davy (Dr. J.), [death], 295; [obituary article], 424
Butler (E. T.), and Prof. M. Polanyi, Influence of Substitution on Organic Bond Strength, 129
Butler (Dr. J. A. V.), Electrocapillarity: the Chemistry and Physics of Electrodes and other Charged Surfaces (*Review*), 536
Buxton (M. B.), [death], 584
Byerly (P.), Seismicity of the Northern Pacific Coast of U.S.A., 270

Caclamanos (Demetrius), Science in its Infancy (*Review*), 76
Cadwallader (C. J.), F. O. Howitt and S. G. Smith, Reversibility of the Denaturation of Silk Fibroin, 301
Cady (G. H.), [C. H. Secoy and], Chlorine Monoxide and Water, 136
Caldin (E. F.), The Functions of Science, 403
Caleb (Prof. C. C.), [death], 328
Callendar (Dr. L. H.), Formation of Protective Films, 304
Calvert (B.), Transformer Insulating Oils, 594
Calvert (E. L.), [A. E. Muskett and], Blind Seed Disease of Rye-Grass, 200
Calvin (M.), M. Kodani and R. Goldschmidt, Salivary Gland Chromosomes, 269
Cammerer (A. B.), National Parks in Conservation, 205
Campbell (K. W. D.), Dual-purpose Cows (*Review*), 285; Farm Management: In-going and Out-going, Insurance, Income Tax, Credit and Farm Records (*Review*), 601
Campbell (N.), Qualitative Organic Chemistry (*Review*), 822
Canterbury (Archbishop of), and others, Racial Freedom and the Colour Bar, 396
Carey (W. F.), Growth of Aggregates in Suspensions, 232
Carlier (Prof. E. W. W.), [death], 360; [obituary article], 452
Carmichael (W.), Treatment of Household Refuse, 83
Carpenter (Prof. G. D. Hale), Dr. R. Hanitsch, 360
Carpenter (Sir Harold), Henry Bessemer and Sidney Gilchrist Thomas (*Review*), 245; [death], 395; [obituary article], 483
Carr (Prof. E. H.), The Twenty Years' Crisis, 1919–1939: an Introduction to the Study of International Relations (*Review*), 209
Cartledge (J. L.), [C. R. Burnham and], Smut Resistance and Interchanges in Maize, 622
Cartwright (C. H.), J. Daniel and A. Petrauskas, Infra-Red Transmission of the Human Body, 591
Case (A. H.), [obituary article], 257
Cassidy (M. C.), [H. S. Booth and], Thiophosphoryl Chlorofluorides, 749
Cave (A. J. E.), Early Iron Age Burial, Bedfordshire, 370
Cawston (Dr. F. Gordon), Blunted Teeth of Lymnœidæ, 654
Cerecedo (Dr. L. R.), Physiology of Pyrimidines, 274
Chadwick (Prof. J.), Excited States of Stable Nuclei, 401
Chain (Dr. E.), [Dr. E. P. Abraham and], An Enzyme from Bacteria able to Destroy Penicillin, 837
Challis (H. J. G.), [Dr. J. Newton Friend, R. H. Vallance and], Phosphate Separation in Qualitative Analysis, 63
Chalmers (Dr. Bruce), Non-parallelism of Lattice Planes in Tin Coatings on Steel, 493
Chamberlain (Neville), death of; activities of, 646
Chambers (late Sir William), Life and Work of, 363
Champion (Dr. F. C.), [Dr. C. F. Powell, H. Heitler and], Neutron-Proton Scattering at High Energies, 716
Chance (M. R. A.), [J. Madinaveitia, Prof. A. R. Todd, A. L. Bacharach and], Mucolytic Activity of Diffusing Factor Preparations, 197
Chandler jun. (R. F.), Cation Exchange Properties of certain Forest Soils in the Adirondack Section, 434
Chapman (F.), Types of Californian Miocene Foraminifera, 63; A New Genus of Fossil Sponges, 809
Chapman (P.), Guidance Programs for Rural High Schools, 743
Chapman (Prof. S.), Dependence of Thermal Diffusion on the Concentration Ratio, 431; Molecular Fields of Force: Retrospect and Suggestions, 607; Molecular Fields of Force, 747
Chasen (F. N.), Hand-list of Malaysian Mammals, 689
Chatt (J.), and F. G. Mann, Phosphonium, Arsonium and Stibonium Salts, 525
Chatterjee (N. C.), [C. F. C. Beeson and], Biological Control of *Lantana aculeata*, 809
Chaudhuri (P. C.), Photographic Proper Motions in the Præsepe Cluster, 307
Chauvisé (Dr. J. M.), Infectious Diseases and Aeroplanes, 363
Cheal (W. F.), Strawberry Yellow-edge Virus, 68
Cheesman (G. H.), D. R. Duncan and I. W. H. Harris, Sodium Polyiodides, 562
Chen (Tze-Tuan), Polyploidy in Paramecium, 68
Chessum (Alfred Stanley), [obituary article], 18
Child (E.), The Tools of the Chemist: Their Ancestry and American Evolution (*Review*), 604
Child (J. M.), [S. Barnard and], Advanced Algebra (*Review*), 665
Chiplonkar (M. W.), Distribution of Temperature in the Lower Stratosphere, 170
Chopra (Brevet-Col. R. N. and Capt. G. S.), Hemp Drug Addiction in India, 487
Chorghade (S. L.), [Prof. K. S. Krishnan, T. S. Ananthapadmanabhan and], Dimorphism of Diphenyl Octatetraene Crystals, 333
Christophersen (E.), and others, translated by R. L. Benham, Tristan da Cunha: the Lonely Isle (*Review*), 821
Clapham (A. W.), Archæology During and After the War, 426

Clark (Prof. A. J.), appointed to the advisory board of the trustees of the Beit Memorial Fellowships for Medical Research, 163
Clark (H. Lyman), Ophiuroidea of the Murray Expedition, 33
Clark (Dr. J. G. D.), New World Origins, 21
Clark (Dr. R. E. D.), Production of Randomness as a Suggested Measure of Intelligence, 369
Clark (Prof. W. E. Le Gros), Anatomical Basis of Colour Vision, 558
Clarke (Dr. J. S.), awarded the Crompton medal of the Institution of Automobile Engineers, 557
Clemens (Dr. W. A.), appointed head of the zoology department of British Columbia University, 490
Cloetta (Prof. Max), [death], 453
Clow (Dr. A.), Deliquescence in Urea and Methyl-ureas, 26
Clynes (J. R.), When I Remember (*Review*), 409
Cochrane (Dr. R. G.), Dr. M. Paulraj and Miss M. D. Salmond, Wheat Diet and Leprosy, 497
Codling (J. H.), Treatment of Abattoir Wastes, 9
Cohen (Dr. J. I.), Mental Tests (*Review*), 46
Cohen (Dr. K.), [Dr. D. W. Stewart and], Isolation of a Heavy Sulphur, 555
Colebrook (F. M.), Field Produced by a Linear Radiator, 35
Colhoun (J.), [A. E. Muskett and], Prevention of Seedling Blight in the Flax Crop, 32
Collier (Dr. H. O. J.), Depression of Neuro-Muscular Transmission in a Crab by Phenothiazine, 232
Collinge (Dr. W. E.), Relation of Museums to Commerce, 526; impending retirement of; work of, 554
Collip (J. B.), H. Selye and D. L. Thomson, Antihormones, 463
Common (Dr. R. H.), Plasma Alkali Reserve in the Domestic Fowl, 98
Compton (Prof. A. H.), awarded the Hughes medal of the Royal Society, 679; work of, 752
Conway (Prof. E. J.), Micro-Diffusion Analysis and Volumetric Error (*Review*), 113
Cook (Prof. E. S.) and C. W. Kreke, Ability of Respiratory-stimulating Factors to Overcome Toxic Action of Germicides on Moulds, 688
Cook (Prof. J. W.), Some Biological Applications of Synthetic Chemistry, 752
Cook (L. G.), [Dr. E. Bretscher and], Production of Actinium C″ from Lead, 430
Cooke (W. B.), Genera of the Pore Fungi, 405
Cooper (Dr. E. R. A.), Human Histology: a Guide for Medical Students (*Review*), 385
Cope (E. T.), and W. F. Kinney, Heat Insulation in Electric Power Stations, 844
Cope (F. W.), A Lower Carboniferous Brachiopod, 690
Coppen (F. M. V.), [Dr. G. W. Scott-Blair and], Compression of Cylinders of Soft Materials, 840
Corder (P.), and C. F. C. Hawkes, Celtic Ornament from Elmswell, Yorks, 433
Corner (H. H.), and Dr. A. M. Smith, Cobalt and Pine Disease, 168
Cort (Henry), Bicentenary of the birth of; work of, 722
Cott (Dr. H. B.), Adaptive Coloration in Animals (*Review*), 144
Coulson (A. L.), Meteorites in the Indian Museum, 299
Coxeter (Prof. H. S. M.), The Generalized Kaleidoscope, 232
Cragg (J. B.), [L. C. Beadle and], Osmotic Regulation in Freshwater Animals, 588
Cramer (R.), [G. B. Kistiakowsky and], Synthesis of Radioactive Lactic Acid, 562
Cramer (Dr. W.), appointed to the staff of the Barnard Free Skin and Cancer Hospital in St. Louis, 300
Crane (M. B.), Origin of the Loganberry, 202; Reproduction in Rubus, 337
Crang (Alice), and Margery Mason, "Growmore" Bulletin, No. 3, 260

Air: -Jet Generator, The Acoustic, Prof. Hartmann, 623; Photography applied to Surveying, Dr. C. A. Hart (*Review*), 572; Raid Shelters: Private, Heating, D. Bellamy, 517; Conditions in, 712; Ventilation of, J. S. Weiner, 733; Raids: What You Must Know: What You Must Do, 125; Survey (*Review*), 572; Raid Damage, 802; 836
Alaska: Disease Among Natives of, Dr. J. D. Aronson, 298; to the Argentine, Highway from, 427
Albanian Fauna, The, 681
Aldehydes, Volatile, liberated by Periodic Acid from Protein Hydrolysates, A. J. P. Martin and R. L. M. Synge, 491
Aleutian Islands Earthquake, 592
Algebra, Advanced, S. Barnard and J. M. Child (*Review*), 665
Aliens: in National Work, Utilization of, 125; Welfare of, 192
Aliphatic Carbon Links, Energy of, E. C. Baughan and Prof. M. Polanyi, 685
All-Electric Laundry, An, 586
Alloys: Corrosion Resistant, H. H. Uhlig and J. Wulff, 562; Application of X-Rays to the study of, Dr. H. Lipson, 798
Alpha, Toxicity of, and Fast Neutron Radiation, R. D. Evans, 621
America: Southern South, Early Explorers of, from the United States, Col. L. Martin, 238; War-time, Recent Impressions of, Dr. J. Needham, 737
American: Conservation Schemes, Some Aspects of, 204; Museum of Natural History, Expeditions of the, 683
Americas, Cultural Unity in the, 673
Amerindian: Religious Reactions to Cultural Impact, Cora Du Bois, 169; Crania, Dr. A. Hrdlička, 336; Relics, 488
Ammonia: in Larvæ of *Lucilia cuprina*, Distribution of, F. G. Lennox, 268; Air-Raid Precautions to be taken by Users of, 518
Amorphous Films, Study of, by Electron Diffraction, Prof. S. Yamaguchi, 333
Ancestral Longevity and the Sex Ratio, P. S. Lawrence, 655
3:6-Anhydrogalactose, Properties of, Prof. W. N. Haworth, J. Jackson and F. Smith, 35
Animal: Coloration and Natural Selection, Sir Edward Poulton (*Review*), 144; Behaviour: Impulse, Intelligence, Instinct, late Dr. J. A. Loeser (*Review*), 317; Dr. E. S. Russell (*Review*), 317; Feeding Stuffs, Wild Seeds as, Dr. R. Melville, 403; Husbandry in India, 457; Biology, Principles of, Prof. L. Hogben. Second edition (*Review*), 545; Breeding: Prof. L. M. Winters. Third edition (*Review*), 667; The Science of, Dr. H. P. Donald (*Review*), 667
Animals, Drinking Habits of, A. Brownlee, 522
Antarctic: Two Men in the, an Expedition to Graham Land, 1920–1922, T. W. Bagshawe (*Review*), 282
Antarctica, Map of, E. P. Bayliss, 22
Anthropoids, Blood Groups of, Prof. J. B. S. Haldane, 652
Anthropology and Administration (*Review*), 380
Antibodies, Structure and Formation of, L. Pauling, 464
Antihormones, J. B. Collip, H. Selye and D. L. Thomson, 463
Anti-pernicious Anæmia Principle in Urine, J. F. Wilkinson, 169
Antiseptics in War-time Surgery, Prof. A. Fleming, 680
Anuak of the Anglo-Egyptian Sudan, The Political System of the, Dr. E. E. Evans-Pritchard (*Review*), 279; Prof. C. G. Seligman (*Review*), 279
Apple, Core Disease in the, H. P. Bell, 34
Aquatic Plants, A Manual of, Prof. N. C. Fassett (*Review*), 700
Arc, The, as a Standard of Light, Prof. J. T. MacGregor-Morris, 555
Archæological Remains in the Whitewater District, Eastern Arizona. Part 2: Artifacts and Burials, Dr. F. H. H. Roberts, jun., with an Appendix: Skeletal Remains from the Whitewater District, Eastern Arizona, Dr. T. D. Stewart, 659
Archæology: Fruits of the Renaissance in, Prof. Daryll Forde (*Review*), 213; During and After the War, A. W. Clapham, 426; and Tradition, 455; in the Eastern Mediterranean (*Review*), 505
Arctic and Antarctic (*Review*), 282
Argon, Liquid, Structure of, Prof. K. Lark-Horovitz and E. P. Miller, 459
Armant: Temples of, a Preliminary Survey, late Sir Robert Mond and O. H. Myers; with chapters by Miss M. S. Drower, D. B. Harden, S. A. Huzayyin, R. E. McEuen and Mary I. C. Myers. Text and Plates (*Review*), 664
Army Medical Services in War, Organization, Strategy and Tactics of the, Lt.-Col. T. B. Nicholls. With chapters by Air-Commodore A. S. Glynn, Col. A. R. Laurie and Col. F. G. Lescher. Second edition (*Review*), 314
Arnold Arboretum, Harvard University, Herbarium of the, Dr. A. C. Smith appointed curator of the, 775
Aromatic Compounds in Mineral Oils, Identification and Determination of, Prof. C. Weizmann, Prof. V. Henri and Dr. E. Bergmann, 230
A.R.P. Warden's Warning System, 427
Art, The Measurement of, F. I. G. Rawlins, 292

Arylamines, Restricted Rotation in, R. Adams and L. J. Dankert, 690
As I Remember Him: the Biography of R. S., late Prof. H. Zinsser (*Review*), 761
Atoms in Action: the World of Creative Physics, Prof. G. R. Harrison (*Review*), 760
Attraction Fields *in vitro*, Prof. J. C. Fardon, Rev. G. Brotzge, Sister M. Kenneth Loeffler and Juanita Breit, 619
Australasian Antarctic Expedition, Meteorology of the, 228
Australia: Commonwealth of, Scientific and Industrial Research, Thirteenth Annual Report, 308; Graptolites of, R. A. Keble and Prof. W. N. Benson, 561
Australian: Aborigines, Intelligence of, Dr. Fowler, 195; Soils, Copper-deficient, D. S. Riceman, C. M. Donald and S. T. Evans, 434; Timbers, Shrinkage of, W. L. Greenhill, 557
Australia's Electrical Requirements, 330
Automobile: Construction, Cast Irons in, E. C. Toghill and R. V. Dowle, 208; Research, 691
Awns in Triticum, Genetics of, A. E. Watkins and S. Ellerton, 135
Aztec Herbal, An, Dr. Agnes Arber, 81

Babes in the Darkling Wood, H. G. Wells (*Review*), 822
Banana, Ripening of the, H. R. Barnell, 494
Bananas, Physiology of Storage in, C. W. Wardlaw, 525
Barnacles attached to Birds, G. Ashcroft, 561
Barnard Free Skin and Cancer Hospital in St. Louis, Dr. W. Cramer appointed to the staff of the, 300
Be^{10}, Radioactivity of, Dr. E. Bretscher, 94
Bees, American Foul Brood in, Precautions against, 101; a correction, 163
Beetles Injurious to Timber and Furniture, Dr. R. C. Fisher, 773
Beilby Memorial Fund, Award from the, made to Dr. F. M. Lea, 771
Beit Memorial Fellowships for Medical Research, appointments and elections, 163
Belfast, Queen's University, Prof. D. L. Savory elected M.P. for, 617
Bell Telephone Laboratories, Inc., resignation by Dr. F. B. Jewett of the presidency, and election as chairman of the board of directors of the; Dr. O. E. Buckley appointed president, 834
Benin, Pre-Portuguese Bronze Castings from, Eva L. R. Meyerowitz, 463
Bessemer, Henry, and Sidney Gilchrist Thomas, Sir Harold Carpenter (*Review*), 245
Bibliographical and Intelligence Services, 298
Bibliography, World (*Review*), 630
Biochemistry: Annual Review of. Vol. 9 (*Review*), 383; Progress in, Dr. E. F. Armstrong (*Review*), 383; Carbohydrate, Introduction to, Dr. D. J. Bell (*Review*), 545
Biological Assay, International Standards for, 748
Biology: in Australian Schools, Prof. J. S. Turner and others, 363; Economic, Teaching of, 376; A History of (*Review*), 443; in the Making, Miss Emily Eveleth Snyder (*Review*), 443; Mathematical: V. A. Kostitzin, translated by T. H. Savory (*Review*), 444; Advances and Applications of, Dr. N. Rashevsky (*Review*), 444; Trends in, E. C. R. Reeve (*Review*), 444; Elementary, T. H. Hawkins (*Review*), 570; Intermediate, W. F. Wheeler (*Review*), 570; Applied in War-time, Sir John Russell and others, 813
Bird: A New, from Virginia and its Fate, K. W. Haller, 463; Observations, Egyptian, 614
Birds: Attracting, W. L. McAtee, 21; Colours of, Changes in the, F. H. Test, 269; British, in 1939, 297; of South Africa, The, Dr. Austin Roberts (*Review*), 345; South African, N. B. Kinnear (*Review*), 345; British, The Handbook of, H. F. Witherby, late Rev. F. C. R. Jourdain, N. F. Ticehurst and B. W. Tucker. Vol. 4: Cormorants to Crane (*Review*), 411; of Britain (*Review*), 411; North American, More Life-Histories of, A. C. Bent, 689; Courtship and Display Among, C. R. Stonor (*Review*), 794; Sexual Display in, Dr. F. H. A. Marshall (*Review*), 794
Black Rust Control, Vocational Training and, 457
Blastocladia Pringsheimii, Life-cycle of, Elizabeth Blackwall, 495
Blockade, Food Supplies and the, 785
Blood Transfusion, History of, Dr. E. Ecale, 228
Blow-Guns for Clearing Away Dust in Factories, 259
Boats, Plank-built, Bark Canoe, Dugouts and, J. Hornell, 336
Body Build, Prof. R. Pearl, 33
Bomb 'Blast': Windows and, 435; Window Breakage by, Dr. H. Moore, 657
Books and Periodicals: for Interned Scientific Men, Dr. W. A. Wooster, 100; Sales Tax on, 192
Borden medal and prize for research in nutrition, award of the, to Prof. H. C. Sherman, 365
Botany, Fossil, Studies in, Dr. R. Crookall (*Review*), 249
Boyle, Robert, Work of, M. Schofield, 488
Brachiopod, A Lower Carboniferous, F. W. Cope, 690
Bracken, Eradication of, 682
Branchiobdellidæ from North America, C. J. Goodnight, 371
Brassica, Cytogenetics of, S. M. Sikka, 524
Brewing: Science and Practice, H. Lloyd Hind. Vol. 2: Brewing Processes (*Review*), 248; Science in (*Review*), 248
Bristol University, Damage to the great hall of, by air raid, 715
British: Museum: Library Extension, 127; (Natural History), Acquisitions, 162; Gift of T'ang Pottery to the, 262; Pharmacopœia, Changes in the, 309; Standards Institution, P. Good, 406; Flora, Additions to the, 486; Columbia University, Dr. W. A. Clemens appointed head of the zoology department of, 490; School at Athens, The Annual of the, No. 37, session 1936–37, Papers presented to Prof. J. L. Myres in honour of his 70th birthday (*Review*), 505; Fauna, The War and the, 517; Rheologists' Club, Formation of the; Prof. G. I. Taylor elected president, 518; Empire Naturalists' Association, Activities of the, 649; Agriculture in War-time, 725; Museum (Natural History): Economic Leaflets, Nos. 4, 5 and 6, 775; Rheologists' Club: Inaugural Meeting, 781
Broadcasting in India, 709
Bromine, Arc Spectrum of, Hyperfine Structure in the, Dr. S. Tolansky and S. A. Trivedi, 687
Brooklyn Polytechnic Institute, Dr. H. Mark appointed professor of organic chemistry in the, 263
Brown Rot Fungi of Fruit Trees, Dr. H. Wormald, 370
Brown University, Prof. G. Pólya appointed to the mathematics department of, 805
Budapest University, Diseases of Students in, 836
Buffalo Museum of Science, award of the Cornelius Amory Pugsley medal of the, to Prof. W. P. Alexander, 161
Building: Design and Construction: with reference to the new L.C.C. Regulations, F. J. Samuely and C. W. Hamann. Vol. 1 (*Review*), 347; Modern, Principles of (*Review*), 347
Bull- or Gopher-snakes (*Pituophis*), Variations in the, Olive Griffith Stull, 524
Burma Government, Impending retirement of Prof. D. H. Peacock from service of the, 715
Buschi: Vom Orang-Säugling zum Backenwülster, Prof. G. Brandes (*Review*), 150
Bush Differential Analyser and its Applications, The, Prof. D. R. Hartree, 319
Business: Management (*Review*), 574; Enterprise, The Economics of, Prof. W. Rautenstrauch (*Review*), 574

Calculus, Advanced, Dr. C. A. Stewart (*Review*), 730
Californian Trout, J. O. Snyder, 494
Cambridge: University Botanic Garden, F. G. Preston, 126; Pleistocene Climate, A, Dr. L. Hawkes, 560; University, conferment of honorary degrees on Prof. A. M. Carr-Saunders, Prof. F. L. Hopwood and Prof. A. E. Richardson, 775
Cambridgeshire, A Flora of, with an Appendix on the Origin and Drainage of the Fens, Dr. A. H. Evans (*Review*), 250

Cameroon Mountains, A French Expedition to the, R. Paulian, 85

Camouflage: in its Application to Ships at Sea, Sir John Graham Kerr, 161; in War-time, C. H. Rowe, 168; Colour-Blindness and, 226; in Modern Warfare, Prof. T. R. Merton; the writer of the article, 429; in War-time, S. K. Thornley; C. H. Rowe, 462; The Progress of, 482; 584; in Modern Warfare, 597; Psychology and, Dr. H. J. Eysenck, 620

Canada: National Research Council of, Twenty-second annual report of the, Major-Genl. A. G. L. McNaughton, 106; Hydraulic Structures, Research in, 331; Royal Society of, annual meeting of the; Organization and work of the, Dr. R. W. Boyle, Dr. H. M. Tory presented with the Flavelle medal, 171; Principal R. C. Wallace elected president, 172; Scientific Research in, Help for, 458

Canadian: Entomological Service, Dr. A. Gibson, 90; Seismological Stations, 804

Canberra, Australia, Stone Implements from, H. P. Moss, 269

Cancer in an Oil Refinery, W. M. Gafafer and Rosedith Sitgreaves, 617

Cancer Research, a forthcoming journal, 805

Carbohydrate, Potassium and, Metabolism, Dr. A. Lasnitzki, 99

Carbon Dioxide: Velocity of Hydration of, in the presence of Extraneous Substances, E. O. Powell, 401; Hydration of, and its Influence on Germicidal Activity of Hypochlorite Aerosols, A. H. Baker and S. R. Finn, 747

Carbonic Anhydrase: Sulphanilamide as a Specific Inhibitor of, Dr. T. Mann and Prof. D. Keilin, 164; Activity of, in relation to Gastric Secretion, W. Feldberg, Prof. D. Keilin and Dr. T. Mann, 651; Keilin and Mann, 779

Cardiac Glycoside ?, A New, C. H. Williams, 303

Carnegie Institution of Washington, Year Book No. 38 of the, 399

Cast Irons in Automobile Construction, E. C. Toghill and R. V. Dowle, 208

Cations at Negatively Charged Surfaces, Concentration of, D. A. Webb and Dr. J. F. Danielli, 197

Cave Worship, Dr. R. R. Marett, 229

Cell: -Division, E. W. Sinnott and R. Black, 68; "Radiations", Prof. J. Ritchie (*Review*), 538

Cellular Respiration, Nature of the Cyanide-stable Portion of, E. A. Houghton Roberts, 461

Cellules reproductrices, l'Origine des, et le problème de la lignée germinale, Prof. L. Bounoure (*Review*), 822

Cellulose Problem in War-time, The, Dr. Julius Grant, 219

Celtic: Ornament from Elmswell, Yorks, P. Corder and C. F. C. Hawkes, 433; West, The, Prof. H. J. Fleure, 649

Central Register, The, 766

Chafer Larvæ in Africa and France, Parasites of, L. A. Moutia, 306

Chance for Everybody: A, a liberal basis for the Organization of Work, H. Dubreuil (*Review*), 284

Channel Islands, Wildfowl in the, 19

Cheese-making: Scientific Research and Control, Prof. H. D. Kay and others, 796

Chelsea Polytechnic, J. C. Crocker appointed head of the chemistry department of, 93

Chemical: Society, Advisory Research Council of the, 124; Industry, Society of, election of officers, 458; Calculations, J. G. Long and H. V. Anderson. Fourth edition (*Review*), 545; Change: The Kinetics of, Prof. C. N. Hinshelwood (*Review*), 603; Prof. E. K. Rideal (*Review*), 603; Lecture Bench, The (*Review*), 666

Chemicals of Commerce, Dr. Foster Dee Snell and Dr. Cornelia T. Snell (*Review*), 543

Chemist, The Tools of the, their Ancestry and American Evolution, E. Child (*Review*), 604

Chemistry: Physical, Practical, Dr. H. W. Melville (*Review*), 5; A New Dictionary of, edited by Dr. S. Miall (*Review*), 280; Alphabetical, Prof. J. Read (*Review*), 280; Forensic, H. T. F. Rhodes (*Review*), 414; Annual Reports on, A. A. Eldridge (*Review*). 416; Applied, Reports on the Progress of, Vol. 24 (*Review*), 416; Progress of, Annual Reports on the, for 1939, Vol. 36 (*Review*), 416; Organic, Institute of, in Moscow, 520; Colloid, a Textbook, Prof. H. B. Weiser (*Review*), 544; Hydrocarbon, a General Discussion held by the Faraday Society, April 1939 (*Review*), 544; Physical, Aids to, R. G. Austin (*Review*), 544; Thermodynamics and, Prof. F. H. Macdougall. Third edition, Prof. J. R. Partington (*Review*), 631; General, Lecture Demonstrations in, Prof. P. Arthur (*Review*), 666; Synthetic, Some Biological Applications of, Prof. J. W. Cook, 752; Organic, Qualitative, N. Campbell (*Review*), 822; of the Hemp Drugs, Prof. A. R. Todd, 829

Chemists, Compulsory Registration of, 125

Chemotherapeutic Agents, a Note on the Modelling of, Pyridine-3-sulphon-(2-pyridyl)-amide, H. McIlwain, 653

Chicago University, Dr. F. C. Koch appointed Frank P. Hixon distinguished service professor of chemistry in, 93

Children: 500 Books for, Nora E. Beust, 23; under Foster Care, J. W. Layman, 262

Chinese Lacquer Toilet-Boxes, Early, B. Gray, 719

Chlorine: Monoxide and Water, C. H. Secoy and G. H. Cady, 136; and Nitric Oxide, Reaction between, E. M. Stoddart, 592

Chloroacetic Acids, Resonance in the, R. P. Bell, 166; E. C. Baughan, 461

Cholesterol Derivatives, Formation of Insoluble Digitonides of, Dr. F. S. Spring and G. Swain, 718

Chromaticity Scales, Colour Vision and, Dr. W. D. Wright, 155; Prof. W. Peddie, 717; Dr. W. D. Wright, 718

Chromatids, Sister, Unequal Breaks in, M. Demerec and E. Sutton, 592

Chromite, Etching Reagent for, J. J. Frankel, 198

Chromosome Changes, Induced Evolution through, Dr. A. F. Blakeslee, 269; Diminution in a Plant, E. K. Janaki-Ammal, 839

Chromosomes, Salivary Gland, M. Colvin, M. Kodani and R. Goldschmidt, 269

Chromospheric Eruptions, Bright, Spectrum of, C. W. Allen, 749

Cilicia, Stone Age, M. C. Burkitt, 58

Cincinnati University, Dr. M. A. Logan appointed Andrew Carnegie professor of biochemistry in the College of Medicine of, 490

Citrus Fruit, Control of Moulds on, J. E. van der Plank, 370

City and South London Railway, Jubilee of the, 743; a correction, 805

Civic Development under War Conditions, 517

Cleveland Museum of Health and Hygiene, Dr. B. Gerhard appointed director of the, 399

Clock, Moving, The Rate of a, Prof. H. Dingle, 391

Coal: Composition of, R. Belcher and R. V. Wheeler, 525; and Coke, Analysis of, Methods of, 773

Cobalt and Pine Disease, H. H. Corner and Dr. A. M. Smith, 168

Cocarboxylase, Prof. R. A. Peters, 387

Coelacanth Fish, Latimeria, The existing, Sir Arthur Smith Woodward, 590

Coelacanthid Fish from South Africa, A Living, Prof. J. L. B. Smith, 53

Coke: and its Properties, H. J. Hodsman (*Review*), 573; The Quality of, being the Second Report of the Midland Coke Research Committee, Iron and Steel Industrial Research Council, Dr. R. A. Mott and Late Prof. R. V. Wheeler (*Review*), 573

Colchicine Treatment of Daphnia, H. H. Durham and A. M. Banta, 170

Collection ? Where is the —, Dr. C. Davies Sherborn (*Review*), 80

Colloids, Precipitation of, by Electrolytes, H. B. Weiser and W. O. Milligan, 622

Colombia, Diet and Nutrition in, Dr. J. Bejarano, 338

Colombo Museum, P. E. P. Deraniyagala appointed acting director of the, 557

Colonial: Office appointments, 229; 428; 520; 684; 775; Secretary, Dr. H. A. Tempany appointed agricultural adviser to the, 426; Policy: The Future of, 790; During and After the War, Lord Lloyd, 833
Colon-Typhoid Group of Bacteria, Function of Nicotine Acid in the Metabolism of the, Prof. I. J. Kligler and N. Grossowicz, 652
Colour: Vision and Chromaticity Scales, Dr. W. D. Wright, 155; -Blindness and Camouflage, 226; and Music, Dr. W. D. Wright (*Review*), 475; Co-ordination, M. Sargant-Florence (*Review*), 475; Vision, Anatomical Basis of, Prof. W. E. Le Gros Clark, 558; Vision and Chromaticity Scales, Prof. W. Peddie, 717; Dr. W. D. Wright, 718
Columbia University, New York, Prof. T. Dobzhansky appointed professor of zoology in, 775
Comet Okabayasi, 650
Comet, Whipple and a new comet found, 587
Concentration Ratio, Dependence of Thermal Diffusion on the, Prof. S. Chapman, 431
Concentric Conductor Type of High-Voltage Alternators, 70
Concrete, Reinforced, Structural Hinges of, Tests of, R. W. Kluge, 276
Conservation: as a Foundation of Permanent Peace, Hon. G. Pinchot, 183; Reclamation in, Role of, J. C. Page, 204
Construction: Johnson's Materials of, rewritten and revised by Prof. M. O. Withey and J. Aston. Eighth edition (*Review*), 286; Materials of, their Manufacture and Properties, late Prof. A. P. Mills. Second, third and fourth editions, edited by H. W. Hayward. Fifth edition, rewritten and edited by Prof. L. F. Rader (*Review*), 286
Contact Catalysts, Kinetics of, and the Industrial Background, Prof. H. S. Taylor, 768
Contacts and Cultures, 698
Convective Equilibrium and Solar Limb Darkening, A. D. Thackeray, 749
Copepods, Indian, Dr. F. Kiefer, 591
Copernican: Literature, Prof. H. C. Plummer (*Review*), 343; Treatises: Three, The Commentariolus of Copernicus; The Letter Against Werner; The Narratio Prima of Rheticus, translated with Introduction and Notes by E. Rosen (*Review*), 343
Corals: of the John Murray Expedition, Prof. J. Stanley Gardiner and Peggy Waugh, 169; Reef-building, Biology of, Prof. C. M. Yonge, 433
Cornell University, Prof. P. Debye appointed professor, and chairman of the department of chemistry; Dr. B. Rossi appointed associate professor of physics, 163
Cort: Henry, Bicentenary of; Life and Activities of, Dr. H. W. Dickinson, 722
Cosmic: Ray: Particles: Heavy, Absorption of, Dr. W. Heitler, Dr. C. F. Powell and Dr. H. Heitler, 65; Specific Ionization of, Dr. R. L. Sen Gupta, 65; Intensities in relation to Cyclones and Anticyclones, Dr. Y. Nishina, Y. Sekido, H. Simamura and Dr. H. Arakawa, 95; Rays: and Poisson's Law, A. Gibert, 198; at High Altitudes, W. P. Jesse, 527; Ray Protons in Lead, Absorption of, Dr. G. D. Rochester and M. Bound, 745; Rays, Origin of, Prof. R. A. Millikan, 804
Cotton: Polyploids in, S. C. Harland, 622; Minerals in, Translocation of, Phillis and Mason, 779
Cows, Dual-Purpose, K. W. D. Campbell (*Review*), 285
Credit Problems of Families, 458
Crepis, Apomixis in, G. L. Stebbins and E. B. Babcock, 34
Crompton medal of the Institution of Automobile Engineers, award of the, to Dr. J. S. Clarke, 557
Crop Husbandry, British, An Outline of, Dr. H. G. Sanders (*Review*), 79
Crops, Cultivated, in Early England, Dr. H. Holbeck, 754
Cross, The Crooked, Very Rev. Dr. A. S. Duncan-Jones (*Review*), 409
Crustacea, Isolated White Chromatophores of, Response of, to change of Illumination, Dr. F. G. W. Knowles, 131
Crustacean Larvæ, R. Gurney and M. V. Lebour, 404
Cryolite Films on Glass Surfaces, Dr. J. Weir French, 687
Crystalline Surfaces, Grinding and Scratching, R. S. Rivlin, 806
Crystallography, Elementary, Dr. J. W. Evans and Mrs. G. M. Davies. Second edition (*Review*), 544
Cultural Unity in the Americas, 673
Culture: in Scandinavia, Continuity of, A. W. Brøgger; A. Steensberg, 67; Freedom and, Prof. J. Dewey (*Review*), 815
Cultures, Contacts and, 698
Cyanide-stable Portion of Cellular Respiration, Nature of the, E. A. Houghton Roberts, 461
Cyclol C_2 Skeleton, A Patterson Analysis derived from the, D. Riley, 231
Cylinders of Soft Materials, Compression of, Dr. G. W. Scott-Blair and F. M. V. Coppen, 840
Cypriot Jugs, Iron Age, J. A. Stewart, 689
Cysteine, Cystine and, Anærobic Degradation of, Desnuelle and others, 139
Cystine and Cysteine, Anærobic Degradation of, Desnuelle and others, 139
Cytoplasm, Increase in Ultra-Violet Absorption of, after Therapeutic X- and Gamma-Irradiation, Dr. J. S. Mitchell, 272
Czech Culture under German Rule, Dr. Beneš, 126
Czechoslovakia, German Culture in, 614

Dairy Cattle and Milk Production, Dr. C. H. Eckles. Third edition, revised by E. L. Anthony and Prof. L. S. Palmer (*Review*), 285
Daphnia, Colchicine Treatment of, H. H. Durham and A. M. Banta, 170
Darwin, Erasmus, William Withering and, Drs. Ruth Musser and J. C. Krantz, jun., 398
Decapod Crustacea, Correlation between Egg-carrying Setæ and Cement Glands in, A. J. Lloyd and Prof. C. M. Yonge, 334
Decontamination of Electrical Equipment, 468
Dehra Dun, Forest Research Institute, programme of work for 1940–42, 835
Demethylation in the Animal Body, Evidence of, S. W. Stroud, 166
Democracy, Ideals of, President Roosevelt, 124
Determinants and Matrixes, Dr. A. C. Aitken (*Review*), 665
Diabetics, Extra Fat Allowance for, 196
Diatom, Peculiar Water Relations of a, D. Bhatia, 591
Diborane Diphosphine, L. Gamble and P. Gilmont, 69
Dielectrics, Solid, Electric Strength of some, 594; A. E. W. Austen and S. Whitehead, 595
Differential Equations, Ordinary, Integration of, Dr. E. L. Ince (*Review*), 665
Diffusing Factor Preparations, Mucolytic Activity of, J. Madinaveitia, Prof. A. R. Todd, A. L. Bacharach and M. R. A. Chance, 197
Diffusing Factors, Madinaveitia and others, 68
Digitonides, Insoluble, Formation of, of Cholesterol Derivatives, Dr. F. S. Spring and G. Swain, 718
Dionne Quintuplets, The, 587
Dioscorea in the East, An Account of the Genus, Part 2: The Species which Twine to the Right; with Addenda to Part 1, and a Summary, Sir David Prain and I. H. Burkill (*Review*), 503
Diphenyl Octatetraene Crystals, Dimorphism of, Prof. K. S. Krishnan, S. L. Chorghade and T. S. Ananthapadmanabhan, 333
Dipole: Moments and Structures, C. P. Smyth, G. L. Lewis, A. J. Grossman and F. B. Jennings, 136; Moment, Ionic Character and, F. T. Wall, 271
Direct: and Alternating Currents: Theory and Machinery, E. A. Loew. Second edition (*Review*), 668; Current Machinery, Prof. H. S. Bull (*Review*), 668
Direction Indicator for an Aeroplane, A new, Dr. D. Luck, 299
"Discovery" Expedition, Crinoids from the, D. Dilwyn John, 236
Divining Rod, The Physics of the, J. C. Maby and T. B. Franklin (*Review*), 150

Drosophila: Species the F_1 Hybrids of which are Sterile, Recombinants between, Dr. H. J. Muller and Dr. G. Pontecorvo, 199; Chromosomes of; Structural Changes in the, Dr. H. J. Muller, 236; Straw Locus in, Somatic Mutations of the, Dr. C. H. Waddington, 335; Development of Wings in, Dr. C. H. Waddington, 689
Drug Cultivation, Empire, 454
Drugs and War-time Alternatives, 496
Dublin Institute for Advanced Studies, Foundation of the, Prof. E. Schrödinger appointed senior professor in the School of Theoretical Physics, 679
Dust, Screened, and its Uses, W. B. Strain, 610

Earth: Science: a Physiography, G. L. Fletcher (*Review*), 80; Tremors in Great Britain, 128; Physics of the, 7: Internal Constitution of the Earth, Edited by Prof. B. Gutenberg (*Review*), 181; The Interior of the, Prof. A. Holmes (*Review*), 181; R. Stoneley, 203
Earthing, Practical Aspects of, E. Fawssett, H. W. Grimmitt, G. F. Shorter and Dr. H. G. Taylor, 623
Earthquake: in Tibet, 128; work at Toledo, Spain, 337; Aleutian Islands, 592; Imperial Valley (California), 622; in Rumania, 647; the Rumanian, of November 10, E. Tillotson, 675; in Chile, 775; Travel-times and Structure South of St. Louis, E. J. Walter, 809
Earthquakes: Recent, 93; Registered at Hong Kong, 93; in the Aleutian Islands, 102; Recent, 196; July, Registered at Kew, 263; of South and Central America, B. Gutenberg and C. F. Richter; H. H. Heck, 270; Japanese, January–June 1939, 307; of the U.S. Atlantic Coastal Plain, H. H. Heck, 307; July, 364; Registered at Hong Kong, 405; and Structures, D. L. Thornton, 437; Recent, 490; in Rumania and Turkey, 615; during October, 719; Registered in Switzerland, 720; Recent, 803
Earth's Crust, Adjustments of the, Physical Controls in, Prof. N. L. Bowen, 563
East: African Islands, Faunistics and Ages of the, R. E. Moreau and R. H. W. Pakenham, 462; Africa, Electric Supply in, 836
Easter Island: Ethnology of, A. Métraux, 465; Origins, 465
Echinoderms from the John Murray Expedition, T. Mortensen; H. L. Clark, 33
Eclipse, A Non-Historical, C. J. Westland, 718
Economic Resources and their Employment, Dr. W. C. Mitchell, 575
Education: Elementary, What is it?, 489; for the Future, 695; for Democracy in Our Time, Prof. J. H. Newton (*Review*), 696
Educational Facilities for the Armed Forces, F. W. D. Bendall appointed adviser, 396
Egypt, Recent British Excavations in, Prof. A. M. Blackman (*Review*), 664
'Egyptian Blue', Examination of, by X-Ray Powder Photography, E. M. Jope and G. Huse, 26
Einstein Effect, Derivation of, from Eclipse Observations of 1936, Prof. T. Matukuma, 264
Eire, Demography of, 23
Electric: Distribution Cables, Standardizing, S. W. Melsom, 22; Power in the Ruhr, Storage of, 193; Torches, Supply of, 261; Transmission by Resonance, Origins of, Sir Joseph Larmor, 459; Power Stations Underground, 518; Fan Ventilation, 616; Power Transmission by Alternate Currents, The Principles of, H. Waddicor. Fourth edition (*Review*), 668; Generating Stations, Movable, 775; Tunnel Kilns for Firing Porcelain, H. N. Ramachandra Rao, 842; Power Stations, Heat Insulation in, E. T. Cope and W. F. Kinney, 844
Electrical: Engineering Mathematics (*Review*), 77; Engineers, Institution of, Awards of Scholarships of the, 263; Equipment, Decontamination of, 468; Effects at Chemical Boundaries, Dr. G. S. Hartley (*Review*), 536; Engineers and the War, J. R. Beard, 615; Discharges in Gases (*Review*), 729; Development in Thailand (Siam), 781; Heating, Costs of, F. D. Parker, 814
Electricity: Generating, Rising Cost of, Sir Percival Bower; F. H. Whysall, 92; Static and Dynamic, Prof. W. R. Smythe (*Review*), 446; Problems in Germany, 565
Electrification, Rural, in England, Development of, 92
Electrocapillarity: the Chemistry and Physics of Electrodes and other Charged Surfaces, Dr. J. A. V. Butler (*Review*), 536
Electrochemistry: The Principles of, Dr. D. A. MacInnes (*Review*), 534; Theoretical, N. A. McKenna (*Review*), 534; Fundamentals of, Dr. S. Glasstone (*Review*), 535; and Electrochemical Analysis, Dr. H. J. S. Sand. Vol. 2: Gravimetric Electrolytic Analysis and Electrolytic Marsh Tests (*Review*), 543
Electrolytes, Current Distribution and Throwing Power in, Dr. A. v. Engel, 66
Electromagnetic: Microbarograph, An, 202; Levitation, 398
Electron: Microscope, A New, Drs. L. Marton and V. K. Zworykin, 35; Microscopy, Ultra-Violet and, Prof. L. C. Martin, 288; Compounds, Formation of 3/2, in Alloys of Copper, Silver, and Gold, W. Hume-Rothery, P. W. Reynolds and G. V. Raynor, 528; Diffraction Intensities, S. Fordham, 807
Electrons, Polarization of, by Double Scattering, Dr. C. B. O. Mohr and Prof. H. S. W. Massey, 264
Electroplating, Recent Advances in, 299
Element 85, Isolation of, Dr. W. Minder, 225
"Elephants and Ethnologists", W. B. Gourlay, 21
Embryological History, Dr. F. H. A. Marshall (*Review*), 348
Embryology: The Rise of, Prof. A. W. Meyer (*Review*), 348; A Manual of, the Development of the Human Body, Prof. J. E. Frazer. Second edition (*Review*), 728; Anatomical, Dr. C. H. Waddington (*Review*), 728
Enemy Aliens, Modification in the Terms for the Release of, 300
Energy: Electrical and Mechanical Transmission of, Prof. W. M. Thornton (Andrew Laing lecture), 693; The Conquest of, Prof. J. A. Crowther (*Review*), 760
Engineering: and Industrial Science: Records and Research in, a Guide to the Production, Extraction, Integrating, Storekeeping, Circulation and Translation of Technical Knowledge, Dr. J. E. Holmstrom (*Review*), 7; and Industry, Information and Progress in, Dr. S. C. Bradford (*Review*), 7; Foundation of New York, Annual Report for 1938–1939, 72; Geological Background of (*Review*), 699; Progress and the Social Order, Dr. F. B. Jewett and Dr. R. W. King, 824
Engineers, Professional, Compulsory Registration of, 89
Enzyme, Inactivation of an, E. W. Landen, 690
Epidemiology in the Army, Lt.-Col. J. S. Simmons, 228
Equations, Theory of: New First Course in the, Dr. L. E. Dickson (*Review*), 250; Prof. H. W. Turnbull (*Review*), 665
Equine Encephalomyelitis in the U.S.A., 91
Ergot, Shortage of, 19
Eriophyidæ Studies, Pts. 1–9, Dr. Keifer, 464
Eros, Use of, to Determine the Solar Parallax, Dr. H. Spencer Jones, 203
Europe: The Prehistoric Foundations of, to the Mycenean Age, C. F. C. Hawkes (*Review*), 213; Food Supplies and Nutrition in, 529
European Reconstruction, Food Policy and, 243
Evacuation: and Educational Policy, 439; Survey: a Report to the Fabian Society, edited by R. Padley and Margaret Cole, 439; of the Very Young, 593

Family Allowances, Pamphlet on, 57; (*Review*), 381
Fanning Island, Archæology of, K. P. Emory, 494
Farm: Woodlands, The Management of, C. H. Guise (*Review*), 475; Management: In-going and Outgoing, Insurance, Income Tax, Credit and Farm Records, K. W. D. Campbell (*Review*), 601

Farmer's Guide, Fifteenth issue of the, 399
Farming: Without Soil, Sir John Russell, 448; as a Business, W. Mansfield (*Review*), 601
Fat: an Index of Œstrogen and Progestogen Activity in the Human Endometrium, Dr. J. Gillman, 402
Fault Formation, Plasticity Conditions for, K. Sezawa, 136
Faults, Formation of, Plasticity Conditions for the, K. Sezawa and K. Kanai, 307
Fauna: of British India, including Ceylon and Burma; Protozoa; Sporozoa, Dr. B. L. Bhatia (*Review*), 384; of the Caspian, Replenishing the, 714
Fear and Courage, The Psychology of, Dr. E. Glover, 361
Feeding-Stuffs: Animal, The Supply of, Dr. N. C. Wright, 251; Britain's Supplies of, Dr. N. C. Wright, 362; in Great Britain, Production of, Dr. N. C. Wright, 712
Ferns: Welsh, a Descriptive Handbook, H. A. Hyde and A. E. Wade, 743
Fertilization, Combined, and Apomixis, G. Gentcheff and A. Gustafsson, 434
Feulgen Reaction: with Nucleic Acid, Nature of the, C. S. Semmens, 130; H. N. Barber and J. R. Price, 335; 808
Fibroblastic Sarcomatous Cells derived from a Dibenzanthracene Mouse Tumour, Architecture of Colonies of a Pure Strain of, Dr. F. Jacoby, 301
Filament Lamps, Fire Risk from the Smashing of, 162
Films, Protective, Formation of, Dr. L. H. Callendar, 304
Fire Alarm System in the United States, F. Cushman and H. A. Friede, 408
Fish: Conservation, Land Utilization and, E. Higgins, 206; Freezing and Cold Storage of, G. A. Reay, 782
Fisheries Research in Hong Kong, Dr. Lin, 207
Fishes, Indian, of Economic Value, 657
Fitzwilliam Museum, Cambridge, Accessions to the, 126
Flax Crop, Prevention of Seedling Blight in the, A. E. Muskett and J. Colhoun, 32
Flies, British Blood-sucking, Dr. F. W. Edwards, H. Oldroyd and Dr. J. Smart (*Review*), 447
Flooded Power Station, A, F. A. Matthews, 364
Flour: White, Reinforced, Dr. T. Moran and Prof. J. C. Drummond, 117; Diastatic Activity of, Damaged Starch and the, C. R. Jones, 202; Vitaminization, Advisory Committee, assistance of specialists to the, 684
Fluids, Ore-forming, Nature of, L. C. Graton, 68
Fluorescence, Photosynthesis and, E. D. McAlister and J. Myers, 621
Fluorine in Industry, Exposure to, W. Machle and E. E. Evans, 330
Folklore, English, Christina Hole (*Review*), 215
Food: and Welfare, F. L. McDougall (*Review*), 243; Policy: and European Reconstruction, 243; 258; Control, its Public Health Aspects, Dr. J. H. Shrader (*Review*), 385; Supplies and Nutrition in Europe, 529; from Producer to Consumer (*Review*), 632; Supplies in Peace and War, Britain's, C. Smith (*Review*), 632; Production in Great Britain and in Western Europe, Sir John Russell, 702; Supplies and the Blockade, 785
Foreign Policy, Speeches on, Viscount Halifax. Edited by H. H. E. Craster (*Review*), 789
Forest: Resources, Conservation of, C. L. Forsling, 204; Soils, Certain, in the Adirondack Section, Cation Exchange Properties of, R. F. Chandler, jun., 434; Research in India and Burma, Part 1, 1938–39, 519
Forestry, Colonial, and Countryside Problems, 567
Forthcoming Books of Science, 547
Fossil Orthoptera Ensifera, Dr. F. E. Zenner. Text and Plates (*Review*), 150; Plants, An Introduction to the Study of, Prof. J. Walton (*Review*), 249; Primate, New, from Sterkfontein, South Africa, J. C. Middleton Shaw, 489; Birds of North America, Check-List of, A. Wetmore, 561
Fowl, Genetics of the, F. B. Hutt and W. F. Lamoreux, 236; Leukosis *in vitro*, Cultivation of the agent of, Prof. L. Doljanski and M. Pikovski, 302
Français, Les, de Grande Bretagne, André Labarthe, 329
France, Depopulation in, Dr. H. Birnbaum, 427
France Libre, La, No. 1, 742
Fraunhofer Lines, Faint, Variation of, M. G. Adam, 780
Freedom: Man's Passion for, General Smuts, 124; and Culture, Prof. J. Dewey (*Review*), 815
Freehand Drawing and Pictorial Illustration for Draughtsmen, W. H. Kerry and E. W. Stott, 457
French: Men of Science in Britain, 73; Scientific Services in Britain, Organization of, 89; Commission gold medal, award of the, to Dr. J. Raynal, 836
Friction and Surface Finish, Prof. J. C. Hunsaker, 138
Frogs, Origin of, D. M. S. Watson, 404
Fuel and Allied Industries, Guide to, 397
Fungi, Higher, Constituents of the, L. C. Cross, C. G. Eliot, Prof. I. M. Heilbron and E. R. H. Jones, 102
Fungicidal Fertilizer, A, S. C. Teng, 102
Fur Animals, Nutrition of, C. E. Kellogg, 364

Galactic: Clusters, A Photographic Survey of, G. Alter, 69; Rotational Constant, The *K* term and the, Dr. W. M. Smart, 103
l-Galactose as a Component of a Polysaccharide of Animal Origin, D. J. Bell and Dr. E. Baldwin, 559
Galapagos: Finches, Evolution of the, D. Lack, 324; a Zoological Landmark, 803
Gall Midge of Grasses, Greenkeeping Matters and the, 261
Garden Plants of the Future, F. Kingdon Ward, 34
Gases: Van der Waals Adsorption of, S. Brunauer, L. S. Deming, W. E. Deming and E. Teller, 371; Kinetic Theory of; An Introduction to the, Sir James Jeans (*Review*), 535; Prof. S. Chapman (*Review*), 535; Electrical Discharge in, Fundamental Processes of, Prof. L. B. Loeb (*Review*), 729
Gastric Secretion, Activity of Carbonic Anhydrase in relation to, W. Feldberg, Prof. D. Keilin and Dr. T. Mann, 651
Genes, Pleiotropic Effect of, J. J. Schwab, 102
Genetics: and Long-day Plants, T. M. Little, J. H. Kantor and B. H. Robinson, 135; and Plant-breeding, J. B. Hutchison; V. G. Panse, 404; and the Study of Development, Prof. J. B. S. Haldane (*Review*), 413
Geology: and Early Man: I, T. T. Paterson, 12; II, T. T. Paterson, 49; and Engineering, Prof. R. F. Legget (*Review*), 699
Geomagnetic Research in the Americas, Dr. J. A. Fleming, 273
Geometry, Elementary (*Review*), 78
Geomorphology: A. A. Miller (*Review*), 445; an Introduction to the Study of Landscapes, Prof. A. K. Lobeck (*Review*), 445; A Textbook of, Prof. P. G. Worcester (*Review*), 445
Geophysics, Submarine Geology and, Prof. F. P. Shepard, 431; Dr. E. C. Bullard, 432
George Cross: and Medal, Institution of the, 425; award of the, to Dr. A. D. Merriman, 744
Germany: Organized Labour in, 260; Electricity Problems in, 565
Germany's Aluminium Industry, 713
Germicides on Moulds, Ability of Respiratory-stimulating Factors to overcome Toxic Action of, Prof. E. S. Cook and C. W. Kreke, 688
Gestation Period, Average, and $n\pi$, Dr. J. H. Kenneth, 620
Gibraltar, Health on, Major R. A. Mansell, 744
Glacial Deposit, Depth of, Determination of the, L. D. Leet and T. J. Smith, 810
Glasgow University, Engineering in, 487
Glass: -making in Nupe, Nigeria, S. F. Nadel, 134; Strain Testing of, Standard Disks in the, E. J. Gooding, 780; Softening Point of, Dr. J. T. Littleton, 810
Gluten Protein, Dr. A. G. McCalla and N. Gralén, 60
Gmelins Handbuch der anorganischen Chemie, Achte Auflage: System-Nummer 22, Lief. 6; Lief 7 (*Review*), 318; System-Nummer 59: Eisen. Teil FII, Lief. 2: Nachweis und Bestimmung von Fremdelementen in Eisen und Stahl; System-Nummer 59: Eisen. Teil C, Lief. 2: Prüfung der Kerbschlagzähigkeit (*Review*), 447; System-Nummer 27: Magnesium. Teil B, Lief. 4: Schluss der Verbindungen, Technische Darstellung der Magnesiumverbindungen (*Review*), 545; Achte Auflage. System-Nummer 35: Alumin-

ium. Teil A, Lief. 6 : Legierung von Aluminium mit Mangan bis Rhenium (*Review*), 668 ; Achte Auflage. System-Nummer 66 : Osmium, mit einem Anhang über Ekaosmium ; System-Nummer 68 : Platin. Teil A, Lief. 1, Teil B, Lief. 1 (*Review*), 759

Golf Green Research and the War, 194
Golgi Apparatus as an Indicator of Secretory Activity in Pancreatic Islet Cells, Dr. E. Vasquez-Lopez, 589
Grain Destruction by Insects, Dr. A. D. Imms, 238
Graphite, Hull-Debye-Scherrer Spectrum of, Anomalous Diffractions in the, A. Taylor and D. Laidler, 130
Graptolites of Australia, R. A. Keble and Prof. W. N. Benson, 561
Grasshoppers, Wild, Translocation in, M. J. D. White, 68
Grassland, Improvement of, 456
Greece : Attack on, 584 ; Appeal to mathematicians for help and sympathy for, 647 ; The Universities' debt to, 742
Greenkeeping Matters and the Gall Midge of Grasses, 261
Greenland Journey : the Story of Wegener's German Expedition to Greenland in 1930–1931 as told by members of the Expedition and the Leader's Diary. Edited by Else Wegener, with the assistance of Dr. F. Loewe. Translated by Winifred M. Deans (*Review*), 282
Group : Theory, J. H. C. Whitehead (*Review*), 44 ; Representations, The Theory of, Prof. F. D. Murnaghan ; F. G. W. Brown (*Review*), 283
Groups : Topological, Prof. L. Pontrjagin. Translated by Emma Lehmer (*Review*), 44 ; the Classical, their Invariants and Representations, Prof. H. Weyl (*Review*), 44 ; The Theory of Group Characters and Matric Representations of, Prof. D. E. Littlewood (*Review*), 699
"Growmore" Bulletin No. 3, Alice Crang and Margery Mason, 260
Growth : -Rates, Relative, Terminology of, Dr. J. Needham and I. M. Lerner, 618 ; Differential Periodic Theory of, G. F. Sleggs, 621
Gull, Black-headed, Nesting Conventions of the, F. B. Kirkman, 655
Gypsies : of the Sárrét (Hungary), I. Nagy, 305 ; Serbian, Disappearance of, Dr. A. Petrovič, 336

Hagiological Healing, C. G. Loomis, 20
Hamilton, Sir William Rowan, The Mathematical Papers of, Vol. 2 : Dynamics. Edited by Prof. A. W. Conway and Dr. A. J. McConnell (*Review*), 180
Hamilton's Dynamics, A. S. Ramsey (*Review*), 180
Harbour Engineering, Early, Sir Leopold Saville, 615
Harvard University, Dr. P. C. Mangelsdorf appointed professor of botany in, and assistant director of the botanical museum, 300
Health : and Occupation, Dr. May Smith (*Review*), 6 ; in relation to Occupation, Dr. H. M. Vernon (*Review*), 6 ; and Industry, 375
Heat Phenomenon, A New Conduction of, G. W. Stewart, 562
Hebe, Male Sterility in, O. H. Frankel, 34
Helium in Rocks, Interatomic Forces and, N. B. Keevil, 656
Heminerus deceptus Rehn, var. *ovatus*, Structure of, and the Classification of Dermaptera, P. J. Deoras, 201
Hemp : Drug Addiction in India, Brevet-Col. R. N. and Capt. G. S. Chopra, 487 ; Drugs, Chemistry of the, Prof. A. R. Todd, 829
Herbage Plants in Scandinavia and Finland, Breeding of, S. Nilsson-Leissner, F. Nilsson, E. Åkerberg, R. Torssell, H. N. Frandsen, H. Waxelsen and O. Pokjakalliv, 22[illegible]
Herbal, An Aztec, Dr. Agnes Arber, 81
Herbs, English, The Season's, 193
Heron, The Fishing, Miss A. Hibert-Ware, 235
Heterosis, I. N. Sveschnikova, 719
High : -Frequency : Apparatus, Prohibition of, 329 ; and Magnetic Fields, Biological Effects of, Dr. K. F. Nagelschmidt, 590 ; Voltage Alternators, Operating Experience with, W. D. Horsley, 70
Histamine Shock, Concentrated Plasma in, C. A. Keele and H. H. Kwiatkowski, 32
Histology, Human : a Guide for Medical Students, Dr. E. R. A. Cooper (*Review*), 385
Historian and Scientist : an Essay on the nature of History and the Social Sciences, Prof. G. Salvemini (*Review*), 179
History : and Science : F. S. Marvin (*Review*), 179 ; a Study of the relation of Historical and Theoretical Knowledge, Prof. H. Miller ; F. S. Marvin (*Review*), 316 ; The Materialist Conception of, a Critical Analysis, Dr. K. Federn (*Review*), 600
Holland, Universities of, German Treatment of the, 744
Hominidæ, Classification of, Prof. W. C. Osman Hill, 402
Hong Kong Fisheries Research Station, Journal of the, edited by Dr. G. A. C. Herklots, No. 1, 207
Hormones : Gonadotropic, in the Urine of the Giraffe, Dr. J. F. Wilkinson and P. de Fremery, 491 ; Female Sex, 624 ; Gonadotropic, Prof. P. E. Smith, 624 ; Ovarian Follicular, Prof. E. A. Doisy, 624
Hornbill's Nest, Insect Fauna of a, E. B. Britton, 33
Horticultural Research, Practical applications of, 194
House-Sparrow in New Environment, D. Lack, 809
Household Refuse, Treatment of, W. Carmichael, 83
Human : Jaw, Bony Growths in the, Dr. A. Hrdlička, 524 ; Sex Chromosome, Linkage in the, T. White, 561
Hummingbird : Anna, Note of the, T. L. Rodgers, 305 ; Flight and Habits of the, Dr. W. M. Tyler, 466
Hungary, Roadwork and Bridges in, 195
Hunger !, Heil, Health Under Hitler, Dr. M. Gumpert (*Review*), 529
Huygens, Christian, 1629–1695, A. E. Bell, 511
Hydrocarbons : Physical Constants of, Vol. 2 : Cyclanes, Cyclenes, Cyclynes and other Alicyclic Hydrocarbons, G. Egloff (*Review*), 507 ; Dr. E. F. Armstrong (*Review*), 507
Hydrogen, Perchlorides of, J. A. Wheat and A. W. Browne, 434
Hypochlorate Aerosols, Germicidal Activity of, Hydration of Carbon Dioxide and its influence on, A. H. Baker and S. R. Finn, 747
Hypophysis Secrete a Pancreotropic Hormone ?, Does the, M. Griffiths and Dr. F. G. Young, 266

Iceland, University of, Twenty-ninth anniversary of the, 59 ; P. Sigurdsson, 762
Illegitimate Child, The, C. Mullins, 298

Islamic Culture in London, 712
'Island' Faunas on the Mexican Plateau, Prof. E. H. Taylor, 467
Island: Years, Dr. F. Fraser Darling (*Review*), 474; Naturalist, An (*Review*), 474
Isotopes, Chemical Separation of, Dr. H. C. Urey, 434

Japanese Beetle, Feeding Habits of the, I. M. Hawley and F. W. Metzger, 306
Jericho: The History of (*Review*), 601; The Story of, Prof. J. Garstang and J. B. E. Garstang (*Review*), 601
Jewish-Christian Intermarriages in Budapest, Prof. R. Pearl, 20
Joints, Riveted, and Welded Joints, Prof. B. P. Haigh, 835
Joking Relationships, A. R. Radcliffe-Brown, 305
Jute-growing in the U.S.S.R., 684
Juvenile Delinquents, Treatment of, Dr. H. Pitoux, 298

K term, The, and the Galactic Rotational Constant, Dr. W. M. Smart, 103
Kaleidoscope, The Generalized, Prof. H. S. M. Coxeter; S. Melmore, 232
Karakoram, Map of the, 127
Kinetics of Contact Catalysts and the Industrial Background, Prof. H. S. Taylor, 768
Kingzett's Chemical Encyclopædia: a Digest of Chemistry and its Industrial Applications. Revised and edited by Prof. R. K. Strong. Sixth edition (*Review*), 280
Kitchen Waste for Feeding Farm Stock, J. Beharrell, 47

Laboratory Apparatus, History of, Dr. E. F. Armstrong (*Review*), 604
Labour under Nazi Rule, Dr. W. A. Robson, 260
Lactic: Dehydrogenase, Crystalline, Straub, 69; Acid, Radioactive, Synthesis of, G. B. Kistiakowsky and R. Cramer, 562
Lady-Bird, Genetical Studies on the, Y. Hoshino, 307
Land: The Drift from the, G. V. Jacks (*Review*), 147; Utilization and Fish Conservation, E. Higgins, 206; Use and Management, Ecological basis of, P. B. Sears, 309
Lantana aculeata, Biological Control of, C. F. C. Beeson and N. C. Chatterjee, 809
Latimeria, the surviving Crossopterygian Fish, Sir Arthur Smith Woodward, 53
Latin American-Culture, Concerning, edited by C. C. Griffin (*Review*), 674
Lattice Planes in Tin Coatings on Steel, Non-parallelism of, Dr. B. Chalmers, 493
Laue: Photograph, The Extra Spots of the, Sir William Bragg, 509; Photographs, Diffuse Reflections on, Dr. Kathleen Lonsdale, 806
Lavender Oil, Shortage of, H. S. Redgrove, 304
Lead Salts, Solubility of, S. M. Edmonds and N. Birnbaum, 720
Learning, A Tax on, 160
Leeds University: bequest to, by Sir James Baillie, 617; Union, loan of the, to the Government, 681; gift to the Brotherton library of, by Mrs. J. R. Ogden and Family, 715; H. Hartley appointed lecturer in mine surveying in, 715; Textile Studies at, 835
Leicester, A New Museum at, 587
Leisure, Juvenile, Research on, 490
Leprosy: Wheat Diet and, Dr. R. G. Cochrane, Dr. M. Paulraj and Miss M. D. Salmond, 497; in Brittany, Dr. Y. M. Marhic, 684
Leverhulme Research Fellowships, award of, to Prof. J. R. Bellerby, Dr. R. M. Davies, Dr. A. G. Gaydon, Dr. N. A. V. Piercy and W. H. Warburton, 93
Liberty, Let There Be, A. P. Herbert (*Review*), 409
Life: on other Worlds, Dr. H. Spencer Jones (*Review*), 211; The Secret of, Cosmic Rays and Radiations of Living Beings, G. Lakhovsky, translated by M. Clement (*Review*), 538
Light, Absorption of, by Interstellar Matter, Stebbins, Huffer and Whitford, 810
Linear Radiator, Field Produced by a, F. M. Colebrook, 35
Linnean Society, resignation of F. Druce of the honorary treasurership of the; election of Major F. C. Stern as his successor, 650
Little Woodbury, Wilts: Excavation at, the Settlement as Revealed by Excavation, G. Bersu, 841
Li Tribes of Hainan Island, Chungshee H. Liu, 202
Livestock Problems: War-time, Appointment of an advisory committee on, 89
Llys Helig, The Legend of, its Origin and Significance, Dr. F. J. North and W. F. Grimes, 455
Loganberry, Origin of the, M. B. Crane; P. T. Thomas, 202
Lomonosov, M. V. (1711–1765), Prof. J. D. Bernal, 16
London University: Report on the work of, 1939–40, 226; conferment on Dr. W. V. Mayneord of the title of professor, 263; College Library, Air raid damage and loss of life at, 520; conferment of the title of professor on Dr. W. V. Mayneord; award of the Sir John William Lubbock memorial prize to M. G. Pimputkar, 805
Long-Term Prisoner, The, Dr. M. Sukov, 229
Lorisoid Monkeys, Folding of the External Ear of, Prof. W. C. Osman Hill, 494
Lower Atmosphere, Ionization of the, J. J. Nolan, 720
Lucilia cuprina, Distribution of Ammonia in Larvæ of, F. G. Lennox, 268
Lymnœidæ, Blunted Teeth of, Dr. F. Gordon Cawston, 654
Lythrum Salicaria, Non-Lethality of the Mid Factor in, Prof. R. A. Fisher and Dr. K. Mather, 521

McGill University, Montreal, Dr. R. Kroner appointed professor of logic and metaphysics in, 59
McLennan: a Pioneer of Canadian Science, Lord Rayleigh (*Review*), 111; Sir John Cunningham, a Memoir, H. H. Langton. With a chapter on his scientific work by Prof. E. F. Burton (*Review*), 111
Macleod, Col. Kenneth, 90; Dr. H. Harold Scott, 201

McMath-Hulbert Observatory, The McGregor Building and Tower Telescope of the, Dr. R. R. McMath, 287
Macmillan War Pamphlets (*Review*), 409
Madras, Government Museum, Extension to the, 229
Madreporarian Corals of the "Discovery" Expedition, Prof. J. Stanley Gardiner, 67
Magnesium: Deficiency in Fruit Trees, T. Wallace; E. B. Kidston, 337; Surface of, attacked by an Aqueous Chloride Solution, An Electron Diffraction Study of the, S. Yamaguchi, 654
Maize: Cytogenetics of, E. G. Anderson and R. A. Brink, 270; Origin of, Dr. P. C. Mangelsdorf, 338; Smut Resistance and Interchanges in, C. R. Burnham and J. L. Cartledge, 622; Growing Point, A Periclinal Division in the 'Dermatogen' at the Tip of the, Dr. B. C. Sharman, 778
Malachite Green, Adsorption of, by Clays and Allied Minerals, V. L. Bosazza, 334
Malaria: in Costa Rica, A. A. Guzmán, 330; Control, A Handbook of, R. Svensson (*Review*), 823
Malayan Nature Journal, No. 1, 771
Malayan Nature Society, Inauguration of the, 771
Malaysian Mammals, Handlist of, F. N. Chasen, 689
Mammalian Palate, Evolution of the, F. R. Parrington and T. S. Westoll, 655
Mammals, Early, of South America, G. G. Simpson, 270
Man: and Society in an Age of Reconstruction: Studies in Modern Social Structure, Prof. K. Mannheim. With a bibliographical guide to the study of "Modern Society". Translated by E. Shils (*Review*), 3; -Power, Available Resources of, Sir William Beveridge appointed commissioner on, 23; Upright Posture of, Attainment of the, Prof. F. Wood Jones, 26; Early, and Pleistocene Deposits in America, F. C. Hibben, 90; -Power, Scientific, Potential and Real, 141; of the Nation, 258
Manufacturers' Order Book, by "Sala", 683
Marine Biology at Hull, Prof. A. C. Hardy, 105
Marxism: a Post-Mortem, H. B. Parkes (*Review*), 508; in History exposed, F. S. Marvin (*Review*), 600
Massachusetts Horticultural Society, award of the George Robert White medal to Sir Arthur Hill, 684
Materials, Strength of, Dr. A. Morley. Ninth edition (*Review*), 386
Maternal Constitution and Infant Mortality, H. C. Siebert, 236
Mathematical Analysis, An Introduction to (*Review*), 730
Mathematics: applied to Electrical Engineering, A. G. Warren (*Review*), 77; Elementary, from an Advanced Standpoint Geometry, F. Klein, translated by E. R. Hedrick and Prof. C. A. Noble (*Review*), 78; Advanced, Text-books of, Dr. J. A. Todd (*Review*), 665; The Symmetric Group in, G. Higman (*Review*), 699
Matter, Mind and, Dr. C. D. Darlington, 808
Medical: Service in War (*Review*), 314; Research Council, J. Gray Stuart and Sir W. Wilson Jameson appointed members of the, 365
Medicinal: Plant Cultivation, 56; Herb production in Great Britain, 397
Medicine in War-time, Prof. J. R. Marrack, 577
Meiosis: Dr. C. D. Darlington, 433; Studies of, O. H. Frankel, Dr. C. D. Darlington; Dr. C. D. Darlington and L. La Cour, 656
Melbourne University, Dr. K. E. Bullen appointed to the department of mathematics of, 458
Mental: Tests, Dr. J. I. Cohen (*Review*), 46; Disorders in Modern Life: an Outline of Hopeful Treatment, Dr. Isabel Emslie Hutton (*Review*), 547; Hygiene of Old Age, Dr. N. D. C. Lewis, 650
Merchant Shipping in War-time, 275
Merseyside, Social Statistics of, 206
Mesopotamia, Ancient, and the beginnings of Science, Prof. E. A. Speiser, 705
Metalle und Legierungen, Chemische Physik der, Prof. U. Dehlinger (*Review*), 447
Metallurgical Abstracts. Edited by S. C. Guillan. Vol. 6 (New Series), 59
Metals: Photographic Action of, J. A. Reboul, 103; The Physics of, Prof. W. L. Bragg (Norman Lockyer lecture), 275
Meteorites: British Museum (Natural History) Catalogue of, Second Appendix, M. H. Hey, 196; in the Indian Museum, Catalogue of, A. L. Coulson, 299; of the U.S.S.R., Catalogue of, L. A. Kulik, 804
Météoropathologie: Essai de, Physique, Clinique, Thérapeutique, W. Kopaczewski (*Review*), 250
Meteors, Height of, Seasoned Variation in the, R. A. McIntosh, 271
Methylboric Acid, A. B. Burg, 690
Methyl-ureas, Deliquescence in, Dr. A. Clow, 26
Mexican Plateau, 'Island' Faunas on the, Prof. E. H. Taylor, 467
Mice: Male and Female, Relative Kidney Weights of, F. L. Warren, 367; Tails of, Genetics of the, L. C. Dunn, S. Gluechsohn-Schoenheimer and V. Bryson, 689
Microbiology: A Textbook of, Prof. K. L. Burdon. Second edition of "A Textbook of Bacteriology" (*Review*), 149; Studies in, Prof. R. T. Hewlett (*Review*), 149
Micro-Diffusion: Analysis and Volumetric Error, Prof. E. J. Conway (*Review*), 113; in Chemical Analysis, Dr. J. H. Quastel (*Review*), 113
Microseisms: Origin of, J. E. Ramirez, 271; A Seismograph for, 237
Military Training for University Students, 520
Mind and Matter, Dr. C. D. Darlington, 808
Mineral: Resources of South Africa, 714; Products of the British Empire and U.S.A., Dr. W. Cullen, 772
Ministry of Health and the Board of Education, retirement of Sir Arthur MacNalty; appointment of Sir Wilson Jameson as his successor, 684
Miocene Foraminifera, Californian, Types of, F. Chapman; A. M. D., 63
Miracidia of Sheep Liver-fluke, Reactions of, H. J. Griffiths, 464
Miscegenation in South Africa, 357
Mississippi, Upper, Regulation of the, 227
Molecular: Structure, Viscosity and, Dr. H. Mark and Dr. R. Simha, 168; Fields of Force: Retrospect and Suggestions, Prof. S. Chapman, 607; 747
Molecules, Gaseous, Energy of, A. H. Heatley, 35
Molybdenum, Vanadium and, in Clays, Occurrence of, Dr. V. L. Bosazza, 746
Monocotyledons, Fructosans in the, 656
Monolayers, Mobile, Energy and Entropy of Extension and Spreading of, Prof. W. D. Harkins, Dr. T. F. Young and E. Boyd, 406
Monotremata, Development of the, Part IV, Prof. T. T. Flynn and Prof. J. P. Hill, 339
Morbidity and Death-rates in Great Britain, Dr. P. Stocks, 648
Morocco, Shrine and Market in, W. Fogg, 169
Mortality, Seasonal, in England and the United States, Dr. Lewis-Faning, 126
Mosquito: (Diptera, Culicidæ) new to Britain, A Species of, J. Staley, 368; Nuisances in Great Britain, Control of, Lt.-Col. J. A. Sinton and P. G. Shute, 683
Mould Products, Bactericidal Action of, E. C. White, 404
Mound Builders' Temple, Ohio, 455
Mucolytic Activity of Diffusing Factor Preparations, J. Madinaveitia, Prof. A. R. Todd, A. L. Bacharach and M. R. A. Chance, 197
Munition Workers: The Health and Efficiency of, Dr. H. M. Vernon (*Review*), 599; Well-being of, Sir Arthur MacNalty (*Review*), 599
Murder by Children and Adolescents, Dr. L. Begon, 456
Museums: to Commerce, Relation of, Dr. W. E. Collinge, 526; and the Public, 834
Music, Enhanced, Stereophonic Recordings of, L. Biancolli, 174
Musical Ear, The, Ll. S. Lloyd (*Review*), 476
Mycenæan Origins and Chronology, A. B. Wace, 454
Myzus, Genus, American Aphids of the, P. W. Mason, 135

National: Fruit and Cider Institute, Annual meeting of members of the, 71; Defence, A Psychological 'Hinge' in, 74; Parks in Conservation, A. B. Cammerer, 205; War Effort, Science and the, 469; Welfare, Science and, Sir William Bragg, 731; 741
Nation's Larder, The, and the Housewife's Part Therein: a set of Lectures delivered at the Royal Institution of Great Britain in April, May and June, 1940, Prof. J. C. Drummond and others (*Review*), 727
Nature and Psyche, Prof. A. D. Ritchie (*Review*), 531
Nazi and Nazarene, Monsignor Ronald Knox (*Review*), 409
Nematode Parasites of Plants, Dr. T. Goodey, 229
Nematodes, Fungus Parasites of, C. Drechsler, 336
Nervous Anatomy, Problems of, Prof. J. Boeke (*Review*), 571
Neurohistology, Problems of, Prof. D. M. Blair (*Review*), 571
Neurohumors and other Chemical Activators, Fats and Oils as Protective Repositories of, G. H. Parker, 561
Neuro-Muscular Transmission in a Crab, Depression of, by Phenothiazine, Dr. H. O. J. Collier, 232
Neutron: Loss Reaction produced by Deuterons, Mechanism of the, M. Goldhaber, 167; Radiation, Fast, Toxicity of Alpha and, R. D. Evans, 621; -Proton Scattering at High Energies, Dr. C. F. Powell, H. Heitler and Dr. F. C. Champion, 716
Neutrons: in Heavy Elements, Reactions produced by, Prof. E. Fermi, 640; Collisions of, with Deuterons and the Nature of Nuclear Forces, Prof. H. S. W. Massey and Dr. R. A. Buckingham, 776
Newcomen Society: Publications of the, 398; annual general meeting of the, Col. C. E. Davies re-elected president, 682
New: Order, President Roosevelt and the, 679; World: Order: Preparing for a, 209; Some Problems of the, Dr. G. H. Scholefield (Cawthron lecture), 225; Origins, Dr. J. G. D. Clark, 21; York: University, Washington Square College of Arts and Sciences of, Prof. C. Neuberg appointed research professor of chemistry in the, 365; World's Fair, Electric Utilities at the, G. Boyd, 487; Zealand: Department of Scientific and Industrial Research, Fourteenth annual report of the, 497; Health of, 744; World: Populations, Prof. R. Pearl, 772; 783; Order, Tradition in a, 787
Nicotiana Tabacum, Variegation in, K. R. Stino, 170
Nicotinic Acid, Function of, in the Metabolism of the Colon-Typhoid group of Bacteria, Prof. I. J. Kligler and N. Grossowicz, 652
Night: Shining Eyes, E. A. Glennie; Sir Herbert Parsons, 366; Sky: in August, 128; September, 300; October, 428; November, 557; December, 715; January, 836
Nitric Oxide, Chlorine and, Reaction between, E. M. Stewart, 592
Nobel Prize Awards, Postponement of, 520
Noise in Enclosed Spaces, Reducing, 714
Noises of Warfare, Effect of, on the Ear, Dr. T. S. Littler, 217
Nomenclator Zoologicus, Completion of the, 681
Nordic Twilight, E. M. Forster (*Review*), 409
North-East Coast Institution of Engineers and Shipbuilders, awards of the, 263
Northumberland Collections, Antiquities from the, Sidney Smith, 296
Nose-bleeding, Hereditary, H. K. Fink, 561
Notter and Firth's Hygiene, revised by L. C. Adam and E. J. Boome. Tenth edition (*Review*), 547
Nottinghamshire, The Place-Names of, J. E. B. Gover, A. Mawer and F. M. Stenton (*Review*), 820
Nuclear: Resonances, Theory of, G. Breit, 592; Forces, Nature of, Collisions of Neutrons with Deuterons and the, Prof. H. S. W. Massey and Dr. R. A. Buckingham, 776
Nuclei, Stable, Excited States of, Prof. T. R. Wilkins; Prof. J. Chadwick, 401
Nuer: Culture of the, Dr. R. R. Marett (*Review*), 568; The, a Description of the Modes of Livelihood and Political Institutions of a Nilotic People, Dr. E. E. Evans-Pritchard (*Review*), 568
Number Theory, Elementary, Prof. J. V. Uspensky and Prof. M. A. Heaslet (*Review*), 418
Numbers: Modern Elementary Theory of, Prof. L. E. Dickson (*Review*), 418; Theory of, Dr. H. Davenport (*Review*), 418
Nutrient Solution Culture of Plants, W. G. Templeman (*Review*), 633
Nutrition: and the War, Dr. G. Bourne (*Review*), 571; in War-time (*Review*), 571; The Inorganic Elements in, Prof. E. V. McCollum, 658; in the Home, Violet G. Plimmer (*Review*), 727
Nyasa, Tanganyika and, Lakes, Chemistry and Hydrography of, R. S. A. Beauchamp, 253

Oedema, Nutritional, and Dietary Deficiency, J. B. Youmans, 202
Œstrogens, Site of Action of, Dr. J. M. Robson and Dr. J. Adler, 60
Officer Cadets, University Course for, 362
Oil, A New Fine, 810
Oilfields of the United States, Dr. H. D. Miser, 437
Olivine-basalt, Crystallization of, C. A. Anderson, 236
Onions, Dried, 772
Ophiuroid, Culture *in vitro* of the Excised Embryo of an, H. B. Fell, 173
Optic Fibres in the Lateral Geniculate Body, Termination of, Dr. P. Glees, 747
Organic: Bond Strength, Influence of Substitution on, E. T. Butler and Prof. M. Polanyi, 129; Syntheses, Vol. 20 (*Review*), 823
Organisers and Genes, Dr. C. H. Waddington (*Review*), 413
Oriental Fruit Moth, Parasites of the, H. W. Allen, J. K. Holloway and G. J. Haeussler, 719
Ormskirk Potato Research Station, The, Dr. R. N. Salaman, 634
Orokolo: Drama of, the Social and Ceremonial Life of the Elema, F. E. Williams (*Review*), 380
Osiris: Vol. 7. Edited by Dr. G. Sarton (*Review*), 247; *Isis* and, 262
Osmium and Platinum, Chemistry of (*Review*), 759
Osmotic: Behaviour of some Crustacea, Influence of Temperature on, and its bearing on problems of Animal Distribution, N. K. Panikkar, 366; Regulation in Freshwater Animals, L. C. Beadle and J. B. Cragg, 588
Oxford: Electric Supply Undertaking, H. G. Fraser, 556; University, Prof. W. M. Smart appointed Halley lecturer for 1941, 805
Oxidative Phosphorylation in Brain Tissue, Nature of, Dr. S. Ochoa, 267
Oxygen, Production of, by Illuminated Chloroplasts, R. Hill and R. Scarisbrick, 61

Palæobotany, Indian, B. Sahni; R. V. Sitholey; K. S. Rao and S. R. N. Rao, 101
Palæozoic Coral Genera, Index of, W. D. Lang, S. Smith and H. D. Thomas, 195
Panama, Pre-Columbian Burial in, Dr. J. Alden Mason, 330
Pancreatic Islet Cells, Secretory Activity in, Golgi Apparatus as an Indicator of, Dr. E. Vasquez-Lopez, 589
Pancreotropic Hormone? Does the Hypophysis Secrete a, M. Griffiths and Dr. F. G. Young, 266
Para-Amino Benzoic Acid as a Bacterial Growth Factor, Dr. S. D. Rubbo and J. M. Gillespie, 838
Parachute Fishing Net, A, Dr. J. F. G. Wheeler, 683
Paramecium, Polyploidy in, Tze-Tuan Chen, 68
Paris Academy of Sciences, Prof. H. Vincent elected vice-president of the, 263
Pasteur Institute of India, Kasauli, Thirty-eighth annual report, 23
Pasture Grasses, Diseases of, Kathleen Sampson and J. H. Western, 779
Patent Office, Fifty-seventh report of the, 56
Pathology and Bacteriology, Journal of, May, 59
Patterson Analysis derived from the Cyclol C_2 Skeleton, A, D. Riley, 231

Pavlov Prize of the Academy of Sciences of the U.S.S.R., award of the, to Prof. Maria K. Petrova, 490
Peace: A Lasting, Dr. Maxwell Garnett. With some chapters on the basis of German co-operation, Dr. H. F. Koeppler (*Review*), 209; Planning, the, Sir John Herbert Parsons, 230; The Economic Basis of a Durable, J. E. Meade (*Review*), 243; Aims, 833
Pearl Formed around a Rotifer, A. E. Alexander, 370
Pectic Acid, Constitution of, S. Luckett and F. Smith, 525
Penicillin: An Enzyme from Bacteria able to Destroy, Dr. E. P. Abraham and Dr. E. Chain, 837; Morphological Effects of, on Bacteria, Prof. A. D. Gardner, 837
Penobscot Man: the Life-History of a Forest Tribe in Maine, Prof. F. G. Speck (*Review*), 386
Periodicity, Differential, Theory of, G. F. Sleggs, 495
Persia, Western, Archæological Journeys in, Sidney Smith (*Review*), 537
Personality, The Integration of the, Dr. C. G. Jung, translated by S. M. Dell (*Review*), 533
pertussis Antitoxin, Production of, D. G. Evans, 748
Pétain Government of France, dismissal of MM. Huismans, Cain, Laugier and Longchambon, 163
Petroleum: Gases, The Utilization of, Dr. A. E. Dunstan, 185; Conversion of, Production of Motor Fuels by Thermal and Catalytic Processes, Dr. A. N. Sachanen (*Review*), 507
Pharmaceutical: Examinations, New Regulations for, 296; Society's New House, 713
Pharmacopœia, British, Changes in the, 309
Phenological Records in Great Britain, 305
Phenothiazine, Depression of Neuro-Muscular Transmission in a Crab by, Dr. H. O. J. Collier, 232
Phlox, Irregular Flowers in, J. P. Kelly, 34
Phosphate Separation in Qualitative Analysis, Dr. J. Newton Friend, R. H. Vallance and H. J. G. Challis, 63
Photo-Engraving, Electrical, T. Thorne Baker, 372
Photographer Speaks, The, F. J. Mortimer and others, edited by Dr. O. Bloch (*Review*), 350
Photographic Process, The, Prof. J. E. Mack and Prof. M. J. Marton (*Review*), 350
Photosynthesis and Fluorescence, E. D. McAlister and J. Myers, 621
Physical: Education in Great Britain, Sir George Newman, 115; Problems in Industry, 125; Laboratory Practice, Modern, Prof. J. Strong and others (*Review*), 386; Society Colour Group, Formation of the, election of officers, 427
Physico-Chemical Methods, Dr. J. Reilly and Prof. W. N. Rae. Third edition. 2 Vols. (*Review*), 5
Physics, Applied, Education of Workers in, Dr. H. Lowery, 811
Physiology in Health and Disease, Prof. C. J. Wiggers. Third edition (*Review*), 80
Piedmont Glaciers, Rev. W. L. S. Fleming, 371
Pine Disease, Cobalt and, H. H. Corner and Dr. A. M. Smith, 168
Place-Names of Nottinghamshire, The, J. E. B. Gover, A. Mawer and F. M. Stenton (*Review*), 820
Planetarium, The Pinpoint, A. N. Spitz (*Review*), 350
Planning: The Sociology of, Dr. Julian Huxley (*Review*), 3; in Human Society (*Review*), 383
Plans of Men, The, Prof. L. W. Doob (*Review*), 383
Plant: Disease in relation to the Public, Prof. W. Brown (Chadwick lecture), 118; Cell Membranes, Structure and Composition of, W. K. Farr, 153; Diseases, New, W. C. Moore, 337; Protection, The Science of, Dr. E. F. Armstrong (*Review*), 569; Protection: The Scientific Principles of, with special reference to Chemical Control, Dr. H. Martin. Third edition (*Review*), 569; Physiology, Meirion Thomas. Second edition (*Review*), 823
Plasma Alkali Reserve in the Domestic Fowl, Dr. R. H. Common, 98
Platinum, Osmium and, Chemistry of (*Review*), 759
Poisons: their Isolation and Identification, late F. Bamford (*Review*), 414
Poisson's Law, Cosmic Rays and, A. Gibert, 198
Poles, Impregnation of, with Copper Sulphate, Y. Nakazima, 495
Polish Science, Future of, 425
Politics, Science and Pseudo-Science in, Mrs. Barbara Wootton (*Review*), 508
Polyisobutylene, C. S. Fuller, C. J. Frosch and N. R. Pape, 656
Polyploidy: in the Hermaphrodite Groups of Animals, Evidence for, M. J. D. White, 132; in a Prosobranch Mollusc, A Possible Case of, Prof. A. D. Peacock, 368
Polysaccharide of Animal Origin, *l*-Galactose as a Component of a, D. J. Bell and Dr. E. Baldwin, 559
Population: Policies and Movements in Europe, D. V. Glass (*Review*), 381; Ageing, Problems arising from an, Dr. L. J. Dublin, 566
Populations, Ageing of, Prof. R. Pearl, 36
Porcelain, Electric Tunnel Kilns for Firing, H. N. Ramachandra Rao, 842
Pore Fungi, Genera of the, W. B. Cooke, 405
Port Erin, Marine Biological Station, Report for 1939, Prof. J. H. Orton, 58
Portuguese Africa, Native Medicine in, L. de Pina, 67
Post-War World, Planning the, J. R. Beard, 692
Potash Alkalis, Conserving Supplies of, 363
Potassium: and Carbohydrate Metabolism, Dr. A. Lasnitzki, 99; Compounds (*Review*), 318; Heavy, in Plasma, Increase of, Dr. A. Lasnitzki and Dr. A. K. Brewer, 807
Poverty and Unemployment, Post-War, can be Prevented, T. W. Wyatt and D. Caradog Jones (*Review*), 312
Power Station Industry: History of the, Dr. A. Russell (*Review*), 146; The Early Days of the, R. H. Parsons (*Review*), 146
Præsepe Cluster, Photographic Proper Motions in the, P. C. Chaudhuri, 307
Praseodymium, Singly Ionized, Spectrographic Analysis of, G. R. Harrison and N. Rosen, 371
Prehistoric: Village Site, Ontario, 101; Times, The Study of, H. J. E. Peake (Huxley memorial lecture), 763
Pre-Portuguese Bronze Castings from Benin, Eva L. R Meyerowitz, 463
Preserves from the Garden, 260
Press, The Function of the, 39
Pressures, Very High, Attainment of, M. J. Bassett, 103
Primitive Art: Past and Future, Dr. L. Adam, 519
Probability: and Frequency, Prof. H. C. Plummer (*Review*), 114; and Relative Frequency, Dr. A. C. Aitken (*Review*), 114; Concept, The, E. C. Kemble, 464
Production Organization, The Science of, Prof. E. H. Anderson and Prof. G. T. Schwenning (*Review*), 574
Propaganda, Scientific Method in, 1
Propeller Blades, Vibration of, Kerr, Shannon and Arnold, 843
Prospodium, Rust Fungi of the genus, G. B. Cummins, 102
Protein: Solutions, Molecular and Morphological Shape of, Relations between, Dr. A. S. C. Lawrence, Dr. J. Needham and Dr. Shih-'Chang Shen, 104; Solutions with the Co-Axial (or Couette) Viscosimeter, etc., Dr. J. Needham (a correction), 399; Hydrolysates, Volatile Aldehydes liberated by Periodic Acid from, A. J. P. Martin and R. L. M. Synge, 491
Proton, Doubly-charged, The Possibility of Detecting a, by the Photographic Method, Prof. H. J. Taylor, D. Fraser and V. D. Dabholkar, 777
Protozoology, Prof. R. R. Kudo (*Review*), 80
Psychology: Experimental, Society of, award of the Howard Crosby Warren medal of the, to E. R. Hilgard, 263; and Camouflage, Dr. H. J. Eysenck, 620; in War-time, Dr. C. C. Burlingame, 712
Public: Opinion, Assessment of, 191; Health and Advertising, Dr. K. E. Miller, 456
Pueblo: Indian Irrigation Systems, G. E. Stewart, 591; Culture of Arizona, Affinities in the, 659
Punjab Irrigation Research Institute, Report for year ending April, 1938, 37
Purchase Tax: on Books, 19; and Literature, 225
Purple, Visual, Vision and the Photochemistry of, Prof. F. Weigert, 31

Puyallup-Nasqually, The, Miss Marian W. Smith (*Review*), 349
Pyrenomycetes recorded for Britain, G. R. Bisby and E. W. Mason, 748
Pyridine-3-sulphon-(2-pyridyl)-amide; a Note on the Modelling of Chemotherapeutic Agents, H. McIlwain, 653
Pyrimidines, Physiology of, Dr. L. R. Cerecedo, 274

Quadricovalent Complexes, Configurations of, G. N. Tyron and S. C. Adams, 103
Quantitative Inorganic Analysis: A Treatise on, with special reference to the Analysis of Clays, Silicates and related Minerals, late Dr. J. W. Mellor and H. V. Thompson. Second edition (*Review*), 385

Rabbit, Flemish and Smaller Types of, Fertility in, W. King Wilson, 721
Racial Freedom and the Colour Bar, Archbishop of Canterbury and others, 396
Radiation and 'Stuffiness', K. W. Yarnold and H. D. N. Fitzpatrick, 62; A. R. Pearson, 232
Radio: Echoes and Fading, J. A. Pierce and H. R. Mimno, 34; Educational, Pioneering in, Dr. C. G. Abbot, 227; Active Indicators, Mixed, in Physiological Experiments, Dr. O. Blüh, 233; Communication, Fundamental Aspects of, H. T. Stetson and others, 450
Rana pipiens Tadpoles, Tumour Induction in, R. W. Briggs, 29
Randomness as a Suggested Measure of Intelligence, Production of, Dr. R. E. D. Clark, 369
Range Conservation, R. H. Rutledge, 205
Raspberry, Selective Fertilization in the, D. Lewis, 135
Rat, 'Congenital' Copper Deposit in the, Dr. G. Brückmann and Prof. S. G. Zondek, 30
Rats, Thyroidectomized, Cardiac Metabolism and Rigor in, Dr. L. Stein and Prof. E. Wertheimer, 521
Rays, Beta and Gamma, Studies in, Prof. J. A. Gray, 171
Reading, College Student's, List of Books for a, Third edition, 299
Reconstruction: Social and Economic, 277; Leadership in, 311; and Town and Country Planning, 479; Post-War, Fundamentals in, 499
Rectifier Plant in Time of War, 397
Registration Order respecting Skilled Men, 229
Re-grassing, Sir George Stapledon, 56
Rehabilitation, Social, 471
Reinforced Concrete Design: The Essentials of, a simplified Text-book with special reference to both Old and New L.C.C. Regulations, and to the code of practice of the Building Research Board, R. F. B. Grundy (*Review*), 347
Religion: Make Your Own, A. Gowans Whyte, 486; Vital, a Brotherhood of Faith, Sir Francis Younghusband (*Review*), 543; Science and, Prof. A. Einstein, 605
Remember, When I, J. R. Clynes (*Review*), 409
Reports, Preparation of, R. Brightman (*Review*), 419
Reproduction, The Physiology of, Dr. F. H. A. Marshall (*Review*), 502
Respiration in the Higher Plant, James and James; Boswell and Whiting, 783
Retail-Store Training, K. B. Haas, 428
Rheology: The Science of, V. G. W. Harrison, 580; in Industry, J. Pryce Jones and others, 781
Rhodesia, Southern, Meteorological Report for year ended June 30, 1939, R. A. Jubb, 127
Road: Travel in Air Raids, 397; Accidents: in July, 617; Visibility and, H. H. Ferguson and W. R. Geddes, 694
Rochelle Salt, Crystal Structure of, Dr. C. A. Beevers and W. Hughes, 96
Rock Engravings on the Indus, Cuthbert King, 101
Roman Policy in Northern Britain, I. A. Richmond, 463
Rothamsted Experimental Station: Department of Plant Pathology of the, F. C. Bawden appointed head of the, 331; N. W. Pirie appointed head of the Biochemical Section of the, 554
Royal: Aeronautical Society, G. Brewer elected president of the, 19; Asiatic Society of Bengal, Year Book for 1939, 296; Society: award of Royal medals to Prof. P. M. S. Blackett and Dr. F. H. A. Marshall, the Copley medal to Prof. P. Langevin, the Rumford medal to Prof. K. M. G. Siegbahn, the Davy medal to Prof. H. C. Urey, the Darwin medal to Prof. J. P. Hill, the Sylvester medal to Prof. G. H. Hardy and the Hughes medal to Prof. A. H. Compton, 679; election of officers, 741; medal awards of the, 750; of Canada, Annual Meeting of the; Organization and work of the, Dr. H. M. Tory; Dr. R. W. Boyle presented with Flavelle medal, 171; Principal R. C. Wallace elected president, 172; of Edinburgh: Proceedings of the, 557; election of officers, 617; Horticultural Society, Dr. J. Hutchinson awarded the Loder Rhododendron cup of the, 805
Rubber: Tree, Notation for Tapping Systems of the, E. Guest, 193; Synthetic, A. E. Williams, 487
Rubus, Reproduction in, M. B. Crane; P. T. Thomas, 337
Rufford Village Museum, 519
Rumanian Earthquake of November 10, The, E. Tillotson, 675
Rumania's Cultural Losses, 362
Rural: Community Organization, Prof. D. Sanderson and Prof. R. A. Polson (*Review*), 385; High Schools, Guidance Programs for, P. Chapman, 743
Rust: Fungus, Extreme Specialization of a, Margaret Fort, 337; Fungi attacking the Thistle, Dr. M. Wilson, 779
Rye-Grass, Blind Seed Disease of, A. E. Muskett and E. L. Calvert, 200; H. H. Glasscock, 368; Dr. M. Wilson, M. Noble and E. G. Gray, 492

Sagittarii, R. W., Investigation of the Period of, P. M. Ryves, 170
St. Kilda, Birds on, E. M. Nicholson and J. Fisher, 235
Salerno, The School of, Dr. H. P. Bayon, 57
Salix Hybrids, Cytological Studies of, A. Håkansson, 464
Salt: Common, as a Preservative, J. E. Hamilton, 133; in the Plant, Upward Movement of, Prof. D. R. Hoagland, T. C. Broyer and P. R. Stout, 340
Salts: Dry, Reactions between, H. L. Link and L. J. Wood, 237; Phosphonium, Arsonium and Stibonium, J. Chatt and F. G. Mann, 525
Savoy Chapel, London, Lighting Installation of the, 331
Sciara, Evolutionary Chromosome Change in, C. W. Metz, 306
Science: Front, 1939, Dr. F. Sherwood Taylor (*Review*), 45; and the Classics, Sir D'Arcy W. Thompson (*Review*), 76; in its Infancy, Demetrius Caclamanos (*Review*), 76; Men of, and the War, 107; in War (*Review*), 112; Practical, in Schools, A. G. Lowndes, 133; and Society, Dr. F. Cyril James, 171; and Civilization, Viscount Samuel (Messel lecture), 175; The Challenge of, 175; —Curse or Blessing?, Prof. H. Levy (*Review*), 176; History: and, F. S. Marvin (*Review*), 179; of, Contributions to the, Prof. H. C. Plummer (*Review*), 247; in War Strategy, 258; Practical, in Schools, E. T. Harris, 268; The Functions of, E. F. Caldin, 403; and Crime, Prof. J. Glaister (*Review*), 414; and the National War Effort, 469; appointment of a Scientific Advisory Committee, 485; Introverted (*Review*), 533; and the Soviet Citizen, Prof. M. Ruhemann, 555; and Religion, Prof. A. Einstein, 605; Exact, in Antiquity, Dr. O. Neugebauer, 625; beginnings of, Ancient Mesopotamia and the, Prof. E. A. Speiser, 705; and National Welfare, Sir William Bragg, 731; 741
Scientific: Advancement, T. H. Hawkins (*Review*), 45; and Industrial Research, Advisory Council to the Committee of the Privy Council for, Prof. A. V. Hill, Sir Felix Pole and Sir Robert Robinson appointed members of the, 557; and Technical Books, Recent,

July 27, iv; August 31, iii; September 28, iii; October 26, 550; November 30, ii; December 28, ii; Training and Administration, W. H. Selvey, 648; Societies in War-time, 755; Equipment and the Laboratory, 805; Method, Cultural Significance of, 815
Sclerotiorine, a Chlorinated Metabolic product of *Penicillium Sclerotiorum*, Van Beyma, T. MacCurtin and Prof. J. Reilly, 335
Scottish Society for Research in Plant Breeding, report for 1940, 520
Seals, Ancient, in the Near East, R. A. Martin, 455
Sedov, The, on a New Expedition, 458
Seismicity of the Northern Pacific Coast of U.S.A., P. Byerly, 270
Seismographs, New, for Boulder Dam, 775
Seismological Observations at St. Louis, 720
Seismology: Progress in, 496; Bibliography of, E. A. Hodgson, April, May and June 1940, 744
Senecio Alkaloids, South African, Dr. H. L. de Waal, 777
Sepia, Dr. D. H. Tompsett (*Review*), 350
Sex and Reproductive Physiology, Recent Advances in, Dr. J. M. Robson. Second edition (*Review*), 502
Sheep Liver-fluke, Reactions of Miracidia of, H. J. Griffiths, 464
Sheep's Brain: Anatomy of the, a Laboratory Atlas for Students of Zoology, Prof. E. A. Briggs (*Review*), 546
Ships, Directional Stability of, Dr. Lockwood Taylor, 563
Short-Wave Emissions, Swiss, P. Borsinger, 58
Siegesbeckia orientalis in Britain, Eric Hardy, 688
Silk Fibroin, Denaturation of, Reversibility of the, C. J. Cadwallader, F. O. Howitt and S. G. Smith, 301
Silverfish Insect, Biology of the, E. Lindsay, 67
Silviculture of the Trees of Trinidad and Tobago, British West Indies, R. C. Marshall (*Review*), 546
Smokeless Air, Fourth war-time issue, 329
Smut Fungi in Egypt, Cultural Control of, G. Howard Jones and Abd El-Ghani Seif-El-Nasr Eff, 135
Snake Vessel from South-Central Africa, C. van Riet Lowe, 370
Social: Order: The New, its Mechanism. Edited by A. H. Mackmurdo, 57; and Technical Training in War-time, 420; Rehabilitation, 471; Progress ?, What is, Prof. L. J. Henderson; C. Brinton, 742; Prof. E. B. Wilson, 743; Order, Engineering Progress and the, Dr. F. B. Jewett and Dr. R. W. King, 824
Sodium Polyiodides, G. H. Cheesman, D. R. Duncan and I. W. H. Harris, 562
Sofia Central Agricultural Experiment Station, Dr. D. Kostoff appointed to the, 715
Soil: Conservation, Dr. H. H. Bennett (*Review*), 415; Conservation of the, G. V. Jacks (*Review*), 415; Bacteria and War Wounds, Dr. H. Nicol, 723
Soilless Culture Simplified, Prof. A. Laurie (*Review*), 633
Solar: Parallax, Use of Eros to Determine the, Dr. H. Spencer Jones, 203; System, Origin of the, R. A. Lyttleton, 310; Eclipse, The Total, of October 1, 1940, Prof. F. J. M. Stratton, 422; Faculæ and Solar Constant Variations, H. Arctowski, 495; Variation, Periodicities in, reflected in Weather, Dr. C. G. Abbot, 564; Eclipse: The Total, of October 1, Dr. H. Spencer Jones, 642; The Next Total, 647; of October 1, Ionospheric Observations during the, J. A. Pierce, A. J. Higgs and Dr. E. C. Halliday, 747; Limb Darkening, Convective Equilibrium and, A. D. Thackeray, 749
Solid Solutions, Crystallization Curves of, Nodal Points on, N. L. Bowen, 562
Sorghum, A. Chimæra in, J. B. Sieglinger, 656
Soul: in Western Philosophy and Science, The Idea of the, Dr. W. Ellis (*Review*), 531; of the Universe, The, G. Strömberg (*Review*), 543
Sound: Waves, Visible, A. Blackie, 369; Transmission: in Buildings: Practical Notes for Architects and Builders, R. Fitzmaurice and W. Allen (*Review*), 417; Technology of (*Review*), 417
South: Africa: The Geology of, Dr. A. L. du Toit. Second edition (*Review*), 214; Geological History and Mineral Resources of, Prof. P. G. H. Boswell (*Review*), 214; Mineral Resources of, 714; African Stone Bead Industry, H. S. Harger, 235; America, Floras of, C. B. Read, 236; M. de Oliveira Roxo, 237; -Eastern Union of Scientific Societies, meeting of June 12, 37; -West England, Outline of, in relation to Wave-attack, Muriel A. Arber, 27
Southern South America, Early Explorers of, from the United States (corrections), 650
Speech, Abnormalities of, and the Development of Language, L. Stein, 33
Spheres, Equal, Symmetrical arrangement of, S. Melmore, 199
Spiritual Values, Total War and, 771
Sponges, Fossil, A New Genus of, F. Chapman, 809
Sporozoa, Indian, Dr. C. A. Hoare (*Review*), 384
Spray Fluids, Spreading of, H. Martin, 135
Springtime the Safest Time, 93
Star, White Dwarf, Mass-Radius Relation for a, Dr. D. S. Kothari, 24
Starch: Damaged, and the Diastatic Activity of Flour, C. R. Jones, 202; Granular, Swelling of, Influence of Combined Phosphoric Acid on the, W. A. Richardson and R. S. Higginbotham, 234; Natural and Synthetic, X-Ray Comparison of, Dr. W. T. Astbury, Florence O. Bell and C. S. Hanes, 558; and its Derivatives, J. A. Radley (*Review*), 823
Stars: The Evolution of the, Prof. G. Gamow; Dr. R. A. Lyttleton and Dr. F. Hoyle, 97; Masses of the, Prof. H. N. Russell and Charlotte E. Moore, 103; Fundamental, Apparent places of, 237; Evolution of the, Dr. F. Hoyle (a correction), 458
Statistical Method from the Viewpoint of Quality Control, Dr. W. A. Shewhart, with the editorial assistance of Dr. W. E. Deming (*Review*), 150
Stearanilide, Binding of Water by, B. A. Toms, 266
Stearic Acid, Substituted Amides of, Hydration of, B. A. Toms, 560
Steel Rails, Testing, 774
Stellar Energy, Accretion and, R. d'E. Atkinson, 271
Stereochemical Types and Valency Groups, Prof. N. V. Sidgwick and H. M. Powell (Bakerian lecture), 70
Stereophonic Recordings of Enhanced Music, L. Biancolli, 174
Stone Age Industries in Wyoming, U.S.A., E. B. Renaud, 134
Stored Products, Entomology of, Prof. J. W. Munro (*Review*), 757
Strata, Orientation of, First use of Current-bedding to Determine, S. I. Tomkeieff, 369
Stratosphere, Lower, Distribution of Temperature in the, M. W. Chiplonkar, 170
Strawberry: Yellow-edge Virus, W. F. Cheal, 68; Red Core Root Disease of, C. J. Hickman, 306
Stress-Strain Diagram, A Lattice, Dr. W. A. Wood and Dr. S. L. Smith, 400
'Stuffiness', Radiation and, K. W. Yarnold and H. D. N. Fitzpatrick, 62; A. R. Pearson, 232
Sub-human Types, Classification of, Dr. R. Broom, 94
Subject Index to Periodicals, 1939 (*Review*), 630
Submarine: Valleys on the Continental Slopes of the North Atlantic, Origin of the, Prof. W. H. Bucher, 407; Geology and Geophysics, Prof. F. P. Shepard, 431; Dr. E. C. Bullard, 432; Canyons, Dr. E. B. Bailey, 493
Suez Canal, The, 647
Sugar Beet, Triploid, H. Peto and J. W. Boyes, 748
Sulphanilamide as a Specific Inhibitor of Carbonic Anhydrase, Dr. T. Mann and Prof. D. Keilin, 164
Sulphur: Dioxide, Structure of, V. Schomaker and D. P. Stevenson, 102; Heavy, Isolation of a, Dr. D. W. Stewart and Dr. K. Cohen, 555
Sun Power, Utilization of, Dr. C. G. Abbot, 744
Sunspots: during 1937, Dr. H. Spencer Jones, 136; and Insect Epidemics, D. S. MacLagan, 748; Over the Sun's Disk, Distribution of, G. H. A. Archenhold, 780
Surface Finish, Friction and, Prof. J. C. Hunsaker, 138
Surgery, Special, in War-time, D. W. C. Northfield, Dr. D. McAlpine, Dr. V. Z. Cope, T. H. Sellors and A. B. Wallace (*Review*), 822

Survivals and Beliefs (*Review*), 215
Swazi: The, an Ethnographic Account of the Natives of the Swaziland Protectorate, B. A. Marwick (*Review*), 380
Swedish Astronomer, A Great, Prof. H. C. Plummer (*Review*), 477
Swiss Postal Railway, 195
Swordfish attacking Vessels, Dr. E. W. Gudger, 261
Sydney Observatory Astrographic Catalogue, 780
Sylviculture: American Applied, Prof. E. P. Stebbing (*Review*), 701; Applied, in the United States, Prof. R. H. Westveld (*Review*), 701
Systematics, New: The. Edited by Dr. J. Huxley (*Review*), 42; Towards the, Dr. J. W. Gregor (*Review*), 42

Tanganyika and Nyasa, Lakes, Chemistry and Hydrography of, R. S. A. Beauchamp, 253
Tannic Acid Treatment of Burns, Pitfalls of the, 803
Taxonomy in the Jungle, Prof. J. Ritchie, 240
Teak Plantations, Weeding Methods in, A. L. Griffith, 91
Technical Report, Writing the, Prof. J. R. Nelson (*Review*), 419
Telephone: Calls, Supersonic Signal Method for, W. K. Brasher and B. P. Moss, 300; and Telegraph Statistics of the World, 556
Television, Significance of, W. E. Tremain, 21
Tell El-Amarna: Letters, A New Translation of the, Prof. S. H. Hooke (*Review*), 177; Tablets, The, edited by Prof. S. A. B. Mercer, with the assistance of Prof. F. H. Hallock in the final revision of the manuscript. Luxor edition. 2 Vols. (*Review*), 177
Tellurium (TeII), Ionized, Atomic Energy Values of, Dr. K. R. Rao and M. G. Sastry, 523
Temperature: Coefficients and Acclimatization, Dr. K. Mellanby, 165; Measurements in Vänern and Götaälv, Angström and Jacobson, 749
Temple (Prof. G.), Electromagnetic Theory (*Review*), 446
Termite Intercastes, New, A. M. Adamson, 655
Tertiary Volcanic Rocks of Victoria, A. B. Edwards and W. Crawford, 622
Tetrahydrofuryl-2-carbinol, Optically active, Complex Rotatory Dispersion of, M. P. Balfe, M. Irwin and Dr. J. Kenyon, 686
Thailand (Siam), Electrical Development in, 781
Thermal Diffusion, Dependence of, on the Concentration Ratio, Prof. S. Chapman, 431
Thermodynamics: and Chemistry, Prof. F. H. Macdougall, Third edition; Prof. J. R. Partington (*Review*), 631; for Chemical Engineers, Prof. H. C. Weber (*Review*), 631
Thiophosphoryl Chlorofluorides, H. S. Booth and M. C. Cassidy, 749
Thomas: Sidney Gilchrist: an Invention and its Consequences, Mrs. Lilian Gilchrist Thompson (*Review*), 245; Henry Bessemer and, Sir Harold Carpenter (*Review*), 245
Thomson, Sir J. J., obituary articles: Prof. J. A. Crowther, 351; Sir William Bragg; Lord Rayleigh; Sir William Dampier, 352; Prof. F. Soddy; Prof. E. V. Appleton, 353; Prof. W. L. Bragg, 354; Sir Owen Richardson; Dr. F. W. Aston, 355; Prof. E. A. Milne; Prof. Max Born, 356; X; Prof. E. H. Neville, 357
Thunderstorms at Karachi, B. N. Desai and S. Mal, 136
Tierischen Instinkte und ihr Umbau durch Erfahrung: Die, Eine einführung in die allgemeine Tierpsychologie, Dr. J. A. Bierens de Haan (*Review*), 317
Tikopia, Size of Family in, R. Firth, 404
Tin Mining, Cornish, C. E. N. Bromehead, 405
Tissue Culture Technique, Use of Desiccated Chick Embryo in, P. R. Peacock and R. I. Shukoff, 30
Totalitarian State, Aspects of the, F. M. Marx; Prof. T. Woody; Prof. H. Kohn; Prof. C. R. Whittlesey; M. J. Bonn; Prof. C. J. H. Hayes, 241
Town and Country Planning, Reconstruction and, 479
Tradescantia Chromosomes, X-Ray Radiation on, A. C. Fabergé, 524
Tradition in a New World Order, 787
Training Procedure, F. Cushman (*Review*), 421
Trans-Canadian Highway, The, 438
Transformer Insulating Oils, B. Calvert, 594
Transition Elements, Magnetic Properties of the, F. Bitter, 405
Travancore: Jungle People of, Marguerite Milward (*Review*), 8; Tribes and Castes, The, L. A. Krishna Iyer. Vol. 2 (*Review*), 8
Trematode, A Prolific, Miss Elizabeth Meyerhof and the Hon. Miriam Rothschild, 367
Trepanning, Primitive, S. Piggott, 616; 621
Trephining in New Britain, J. L. Meacher, 433; (a correction), 617
Trimethylcarbinol as a Cryoscopic Solvent, F. H. Getman, 720
Tristan da Cunha: and its Birds, Seton Gordon (*Review*), 821; the Lonely Isle, E. Christophersen and others, translated by R. L. Benham (*Review*), 821
Truth, The Search for, Prof. H. S. Allen, 637
Tubercularia Fungi, T. Petch, 434
Tuberculosis in Mental Hospitals, Dr. C. A. Wicks, 456
Tulipa: The genus, Sir A. Daniel Hall (*Review*), 379; The Taxonomy of, Sir William Wright Smith (*Review*), 379
Tuna, Refrigeration of, 782
Tungsten: Organic Compounds of, F. Hein and E. Nebe, 237; Parahydrogen Conversion on, D. D. Eley and Prof. E. K. Rideal, 401
Turkey: the Modern Miracle, E. W. F. Tomlin, 89
Turquet de Mayerne, Sir Theodore, Work of, Miss Irene Scoloudi, 773
Twenty Years' Crisis, 1919–1939: The, an Introduction to the Study of International Relations, Prof. E. H. Carr (*Review*), 209
Tyneside: the Social Facts, D. M. Goodfellow, 485
Typesetting, Telegraphic, H. H. Harrison; D. Murray, 713

Ultra: -Violet: Light: Fluorescence Analysis in, J. A. Radley and Dr. Julius Grant. Third edition (*Review*), 216; in Technology (*Review*), 216; Absorption of Cytoplasm, Increase in, after Therapeutic X- and Gamma-Irradiation, Dr. J. S. Mitchell, 272; and Electron Microscopy, Prof. L. C. Martin, 288; Centrifuge, The Air-driven, Dr. F. R. Eirich and Prof. E. K. Rideal, 541
Undulant Fever in Normandy, Dr. M. L. Rose-Legrand, 399
Units: M.K.S., and Dimensions and a Proposed M.K.O.S. System, Prof. G. E. M. Jauncey and A. S. Langsdorf (*Review*), 793; Electric and Magnetic, Dr. L. Hartshorn (*Review*), 793
Unity and Resolution, H.M. the King, 425
Universe? Are We Alone in the, Sir James Jeans (*Review*), 211
University: Students and Compulsory Service, Dr. R. Priestley, 162; College of Ceylon, Dr. I. Jenning appointed principal of the, 399
Uranium: Fission Products of, produced by Fast Neutrons, Dr. Y. Nishina, T. Yasaki, H. Ezoe, Prof. K. Kimura and M. Ikawa, 24; Fixation in Modern Cytological Technique, Advantages of, P. N. Bhaduri and C. S. Semmens, 100
Urea and Methyl-ureas, Deliquescence in, Dr. A. Clow, 26
U.S.A.: Equine Encephalomyelitis in the, 91; National Defence Research Committee, appointment of, 191; Vital Statistics of the, for 1938, 262; Register of Scientific Workers, 361; The Fire Alarm System in the, F. Cushman and H. A. Friede, 408; Oilfields of the, Dr. H. D. Miser, 437; Fatal Accidents in, 456; Average mortality rates for four weeks ending June 15, 458; English Sparrow in the, E. R. Kalmbach, 524; Deaths from Tuberculosis in the, in 1939, 557; President Roosevelt re-elected President of the, 614; Mortality of the, in 1940, 804; Crustal Structure of the, 809; Smallpox in the, 836
U.S.S.R.: Jews in the, 263; Folk-lore of the, 650; Jute growing in the, 684; Meteorites of the, Catalogue of, L. A. Kulik, 804

Vaghers of Okhamandal, S. T. Moses, 269

Valency: Directed, G. E. Kimbell, 69; Groups, Stereochemical Types and, Prof. N. V. Sidgwick and H. M. Powell (Bakerian lecture), 70

Vanadium: Pentoxide, Basic Nature of, O. E. Lanford and S. J. Kiehl, 525; and Molybdenum in Clays, Occurrence of, Dr. V. L. Bosazza, 746

Variations, Calculus of, Aspects of the, J. W. Green (*Review*), 250

Vector Methods: applied to Differential Geometry, Mechanics and Potential Theory, Dr. D. E. Rutherford (*Review*), 665

Vegetable: Crops, Diseases of, Prof. J. C. Walker. New edition (*Review*), 758; Pathology, D. E. Green (*Review*), 758

Vegetables, Preservation of, by Waxing, H. Platenius, 102

Vegetative Propagation in Tropical Plantations, G. St. Clair Fielden and R. J. Garner, 91

Vehicle Radio-Telephone Service, 91

Venezuela, Health Conditions in, Dr. J. G. Alvarez, 836

Ventilation of Air Raid Shelters, J. S. Weiner, 733

Venus: and Jupiter, Daylight Observation of, Dr. A. L. Peck, 162; Atmosphere of, Dr. R. Wildt, 810

Verbena: Genetics of, G. H. Beale, 495; Biochemistry of Flower Pigments in, G. H. Beale, J. R. Price and R. Scott-Moncrieff, 690

Victoria University College, Wellington, N.Z., endowment by H. Valder of a research fellowship in social relations in industry at, 519

NATURE

"To the solid ground
Of nature trusts the Mind that builds for aye."—Wordsworth

Vol. 146 SATURDAY, JULY 6, 1940 No. 3688

SCIENTIFIC METHOD IN PROPAGANDA

THE word 'propaganda' is defined in the Oxford Dictionary as "an organized scheme for propagation of a doctrine or practice" ; unfortunately it has acquired a bad, and recently an even sinister, meaning. There are few things from which the scientific worker reacts more instinctively than propaganda. Indeed, his wholesome and genuine prejudice against the word has sometimes led to less than justice being done to the work and abilities of those of his colleagues who have undertaken the task of expounding or interpreting to the world the results of scientific work and their significance for human welfare. There are spheres in which the essential task of education is not readily distinguished from propaganda, and propaganda itself has its uses as well as its abuses. Even societies which exist primarily for research and inquiry may fail of their purpose if they neglect to bring to the notice of the public whatever results have been obtained.

Prejudices which refuse to recognize the right use of an instrument may have consequences as untoward as those which condone abuse, and scientific workers cannot be entirely absolved from responsibility for the consequences of neglect of the important task of exposition. It is not enough for the Government to make even full use of the service of scientific men in the evolution or execution of a policy. Co-operation of the public is also involved to the extent that it demands an intelligent understanding of the policy, and for this an immense campaign of education is essential.

In their own particular studies, scientific workers have as yet given nothing like the attention to this question that is desirable on general grounds, or, in certain fields such as food supply, that is now essential for the development of our war effort. Some aspects of this work may fairly be regarded as falling within the field of the Ministry of Information, but scientific workers are not entitled to criticize the Ministry unreservedly for shortcomings unless they have made their own contribution, or at least put forward constructive proposals. The dissemination and use of information, as much as the acquisition of information, require scientific study and the application of scientific methods.

This is not a matter which can be left entirely to information services. Their special function is the locating of information and its handling in the most efficient form. Only to a limited and technical extent are they concerned with the form in which it is presented or the use to be made of it. The educational aspect lies almost entirely outside their scope. There are features in the present situation, however, which demand the attention and co-operation of scientific workers.

The question of food supply and policy is only one, though probably the most prominent, of the matters in which inadequate use has been made of the services of scientific workers, and insufficient guidance has perhaps been given by them. Nor is it alone in being essential for the efficient prosecution of our war effort. Lord Chatfield's statement early in the year regarding the co-ordination of the scientific research carried out by the special departments of the Fighting Services and of the Ministry of Supply only partly dispelled misgiving as to the use being made of scientific services in the immediate task of national defence. In many other wide fields similar concern may be felt with even more reason. The recent report of the Industrial Health Research Board of the Medical Research Council on industrial health in war emphasized the need for applying knowledge already gained, rather than for fresh researches, and stressed the need for development of the work arising from the Health of Munition Workers Committee of 1915–17 and the Industrial Fatigue Research Board established in 1918. The report of the Barlow Commission on the distribution of the industrial population of Great Britain and the various inquiries into the success or failure of evacuation schemes provide other examples of the way in which more effective use might be made of existing scientific knowledge in the development of the national welfare, apart from the extension of that knowledge.

Scientific workers have yet to realize that they have a very large responsibility for seeing that much more adequate use is made of the knowledge which they have made available for the community. They must assist much more wholeheartedly in the interpretation of those results to the community, whether to the administrator or to the general public, in order to secure their integration into the general policy and practice of the community. The new Division for the Social and International Relations of Science of the British Association, in the various inquiries it has set going, has already made progress in this field, but much more is required. Men of science should recognize that concern with the social consequences of the application of their discoveries involves attention to the way in which these discoveries are presented to the public, in order to secure as favourable an opportunity as possible for the use of new knowledge for society's weal rather than its woe.

Interpretation or presentation in this sense is inevitably linked up with the question of education, and of securing that the education of every citizen includes at least enough teaching of general science on broad lines to fit him or her to take a place in this world of applied science and to appreciate the scientific outlook. It involves also the use of what may be called rational propaganda—the propagation by reasoned argument of the knowledge and experience and standards of conduct upon which the future of the race, if not of civilization, depends.

Significantly enough, we have come to realize, as was done some twenty-five years ago, that the successful prosecution of the War demands adequate attention to rational propaganda, not merely within our own boundaries but at least in neutral countries also. If it is neglected, or this field left entirely to our enemies, difficulties and misunderstandings may arise, engendering friction or hostility, which may react dangerously on the effectiveness of our policy. We can no more rely on the justice of our cause and the integrity of our ideals, unsupported by wise and fair exposition, to maintain the sympathy of neutrals, than the scientific worker can rely on the statement of his results before a meeting of his fellows to secure the appropriate use of his work in the service of some national interest.

The importance of propaganda as an instrument of foreign policy is well shown by Prof. E. H. Carr in one of the Oxford Pamphlets on World Affairs, in which he not only points out why democratic Governments find it necessary to control and organize opinion if they are not to be at a serious disadvantage in dealing with the Totalitarian States, but also he demonstrates the necessity for some control by the State, however discreetly veiled, over the instruments of propaganda, if the public good is to be served and the community to survive. Even in time of peace, no Government can afford to leave publicity and propaganda in the unguided hands of private interests.

Much of the interest for scientific workers of Prof. Carr's pamphlet is derived from its analysis of the limits and checks on propaganda as well as of its dangers. The tendency of education, itself an instrument of propaganda, whether rational or not, to promote a spirit of independent inquiry, is one of the strongest defences against its wrong use. Further, the more rational the methods by which propaganda is conducted and the more it is in line with the rights and interests not of a section, or class or nation, but of the world community, the more likely it is to be effective.

What has to be recognized is that, although propaganda is an instrument which can be used wisely as well as unwisely, and has its proper place in the maintenance and advancement of order and culture, it is not a scientific inquiry into truth; a balanced exposition of the evidence for or against his thesis cannot fairly be expected from the propagandist. On this ground alone, it is important that institutions such as Political and Economic Planning or the Royal Institute of International Affairs at Chatham House, which have acquired a deserved reputation for the unprejudiced investigation of social, economic and international matters, and the balanced and unprejudiced presentation and interpretation of their findings to the public, should continue their work and be supported by all those concerned in advancing the standard of education and knowledge in the community: although we may regret, perhaps unjustifiably, the closer association of Chatham House with the Foreign Office, as likely to endanger the reputation of the Institute for the impartial examination of such matters. At least it may be hoped that the criticism at present finding expression as to the mode of exposition of Allied policy and aims in the world generally, or the elaboration and execution of domestic policy in Great Britain, may remind the powers that be that scientific workers recognize responsibilities in such fields which they are eager to discharge.

THE SOCIOLOGY OF PLANNING

Man and Society in an Age of Reconstruction
Studies in Modern Social Structure. By Karl Mannheim. With a Bibliographical Guide to the Study of "Modern Society". Translated from the German by Edward Shils. Pp. xxii + 469. (London: Kegan Paul and Co., Ltd., 1940.) 16*s.* 6*d.* net.

PROF. MANNHEIM'S book, we may prophesy, is likely to become the planners' bible, for nowhere else can one find such a complete, up-to-date and well-reasoned analysis of the inevitability of planning, good and bad, and of its techniques. It is, however, more than this rather irreverent comparison would suggest. It is a compendium of modern sociological fact and theory, abundantly documented, woven round the central theme of the planned world's dawning.

Prof. Mannheim was one of the leading sociologists in Germany. With the advent of the Nazi regime, however, he came to Great Britain, and has since been teaching at the London School of Economics. The present volume is a revised and much enlarged edition of an earlier German work published in Holland five years ago. This, as Dr. Mannheim says in his preface, was written when he was "completely under the influence of experiences bred by the disintegrating tendencies of liberal society". He saw how, under certain conditions, the planlessness of the liberal order turned into anarchy. Since then, however, he has been living "in a country where liberal democracy functions almost undisturbed". This enabled him to free himself from his deep-rooted scepticism as to the vitality of democracy in our age. From one aspect, the present volume has become a study, by no means pessimistic, of how planning and order may be combined with the essentials of democracy and freedom.

The formidable extent of the author's learning and background may be gauged by the fact that no fewer than seventy-two pages are taken up with what he calls a "purely personal bibliography", itself elaborately arranged under subjects and subheads.

No reviewer can pretend to give an adequate account of this lengthy and tightly packed book; but a brief summary of the main themes of its six parts will give some idea of its scope.

The first part is a study of the rational and irrational elements in modern social existence. In the mass society of the present day, disastrous tensions develop as a result of the numerous contradictions between the high degree of rationalization in industry and its almost complete absence in politics and ordinary human behaviour. Thus industrial organization becomes a mere façade, behind which irrational force is the *ultima ratio*, both in internal and in foreign politics.

The second study deals with the role of the *élite* in society. Nineteenth century democracy was a 'minority democracy', from whose benefits large sections of the population were formally or virtually excluded. Such a society, however, had one advantage; it permitted the formation of an *élite* which had initiative and could in large measure assume the function of intellectual and cultural leadership. With the rapid transformation of 'minority democracy' to the present phase of 'mass democracy', *élites* multiply and tend to cancel each other out. Cultural leadership fails, and with it arises a widespread contempt for intellect and the things of the spirit. The obscurantist anti-scientific movement of to-day is a symptom of this phase.

Part three treats of war and dictatorship. The author rightly dismisses the idea of war arising inevitably from human aggressive instincts. The problem is how to canalize our plastic impulses so as to avoid war ; like other human problems, it is one of planning and organization. Of extreme interest is his analysis of the Fascist State as a "system of organized insecurity", arising out of the previous disintegrative condition of unorganized insecurity under the guidance of reckless, cynical and unscrupulous groups.

But if insecurity can be organized, why not security ? The discussion of this question occupies the last three parts of the book. Security cannot be organized save by conscious, rational planning ; organization in human affairs does not just happen. But can thorough-going social planning be reconciled with the basic concepts of our Western civilization ? Is it compatible with democracy in any form ?—with liberty ? We observe the planning techniques developed by the new dictatorships for the total manipulation of their peoples, we see that they are fundamentally undemocratic and destructive of human freedom, and we wonder whether this does not apply to any form of planning.

Mannheim argues cogently not merely that this is not true, but also that planning is essential for any new peaceful development (as opposed to a collapse and a slow and painful rebirth) of free human society. Organization is a mechanism, and, like any mechanism, can be used for good or for evil ends.

The liberal or *laissez-faire* age is nearing its definitive end. Mass or 'structural' unemployment cannot be overcome within the old framework. If not countered, it has a destructive effect on society, leading to mass demands for security and social justice which cannot be met except by broad planning. Already in the democratic countries, even in the New World, this is being undertaken, albeit piecemeal, in the shape of large-scale social services. The old negative type of State, concerned mainly with foreign policy and keeping the ring at home, is here giving place to what we may call the Social Service State. The planned all-round development of the Social Service State is the only alternative to the planned Totalitarian Power State—or to chaos.

It would take too long to follow Mannheim through his thorough discussion of the means by which the planned Social Service State may be nursed from its present embryonic condition into full and efficient being. One or two points, however, may be mentioned. An enlarged bureaucracy is a necessary instrument of any planned society ; he stresses the need for not allowing this to become dominant or out of hand. One safeguard against this is the presence of a strong unofficial *élite* ; this can only be maintained in a modern mass-society by an enlarged educational system with new content and aims. Here is to be found at least a partial answer to the perennial question : "Who plans the planners" ? The answer clearly is, that no one attempts such a megalomaniac task ; on the contrary, planning is a continuous and deliberate process, which demands experiment and discussion, check and countercheck. The intellectual *élite*, informed public opinion, the bureaucracy and the Government can act as checks and counterchecks on each other to ensure a balanced growth of this sort.

Finally, in an interesting section, Mannheim points out that liberty is never absolute, but always relative to the social system, and that liberty in a planned society will differ from liberty as we have become accustomed to it in a *laissez-faire* society. It is the correlative of responsibility, and a free planned society can only exist on the basis of many new responsibilities.

No single book can expect to cover this vast field fully. It seems clear that the next step must be a more concrete analysis of the problem in relation to the differences between various nations and to the particular problems before them severally and jointly. It is only a rough first approximation to speak of the Western democratic countries : France, for example, differs radically from Great Britain in many important respects of social structure and outlook, and both from the United States. Again, the relation of the various metropolitan powers to the world's backward colonial areas constitutes a special problem of its own, which the author does not touch upon.

However, for any such more detailed or more concrete studies Dr. Mannheim's book will be an indispensable basis. Metamorphosis in animals is a somewhat cataclysmic process of development. It is no less so in the development of societies. What we are accustomed to call civilization is in the midst of a metamorphosis of which the present war is a symptom. "Man and Society in an Age of Reconstruction" is one of the very few works to deal comprehensively and on an adequate basis of scholarship with this alarming but in the long run hopeful phase of human development.

JULIAN HUXLEY.

PRACTICAL PHYSICAL CHEMISTRY

Physico-Chemical Methods
By Dr. Joseph Reilly and Prof. William Norman Rae. Third edition. Vol. 1: Measurement and Manipulation. Pp. xv+686. Vol. 2: Practical Measurements. Pp. ix+580. (London: Methuen and Co., Ltd., 1940.) 84*s*. net.

PHYSICAL chemists in Great Britain have in the past usually looked to Germany for the provision of those monumental text-books which treat in exhaustive detail and with characteristic thoroughness the various branches of the subject. But in recent years there have been welcome signs that this position will not continue. The number of British texts on that increasing borderland between chemistry and physics is the best evidence that physical chemistry is at last beginning to take an independent and, it is hoped, original outlook on the matter. The two volumes under review form another addition to the ever-growing list.

"Physico-Chemical Methods" has already passed through two editions, and it was inevitable that a third edition must expand, until now the book has been split into two large volumes. The writers of such a comprehensive text are faced with difficulties unknown to the author of a specialized monograph. They cannot themselves be experimentally familiar with the whole field. Consequently they must invite collaborators to write much of the text if this is to be truly representative; at the same time, the whole must be homogeneous. Another difficulty arises in the following way. Much of the apparatus used in physical chemistry has been elaborated by commercial undertakings to such an extent that it is impossible for an ordinary laboratory to attempt to construct it. In a practical text-book, therefore, all that remains to be done is to describe how the apparatus is used; in view of the diversity of designs the authors' task is made all the more difficult. In the present book there is a judicious balance kept between these conflicting claims.

The two volumes are rather arbitrarily divided into measurement and manipulation (Vol. 1) and physical properties (Vol. 2). They are, of course, closely complementary. Vol. 1 opens, as usual, with chapters on measurements and calculations. Then follows a very short chapter on phase rule practice. Admittedly the principles of obtaining phase rule diagrams in sufficiently simple systems are easy enough, but the practice is often extremely difficult. The brevity of this chapter is compensated later on by a full discussion of evaporation and distillation. Next follow a number of chapters on apparatus and laboratory technique. Here there are some excellent up-to-date sections; for example, that dealing with pumps, but perhaps glass working might have made way for more physico-chemical technique.

There is, too, a chapter on high-pressure technique by an expert in the field. The question does arise, however, whether a person not familiar with the technique would be justified on embarking on a programme involving its use, after perusing this chapter. This does not in the least reflect on the merits of the chapter, which forms an excellent introduction to the field—more akin to precision engineering than to chemistry. In the chapters on thermometry and thermochemistry, the thermopile might have been given more prominence, as it is being increasingly used; similarly, there is no description of the disappearing filament pyrometer. Mention of the more recent types of adiabatic calorimeter would also have been welcome.

All the classical practical physical chemistry is described at length in the second volume. It is gratifying to find, too, an account of the technique for dealing with the properties and reactions of monolayers. As might be anticipated, vaporization and fractionation are dealt with in authoritative detail, the recent work on molecular stills taking due prominence in this section. Under the heading solids, mention is made of flotation; filtration, too, gets its share of space, but it is doubtful whether a description should be included of large-scale filter presses. There is also a description of the air-blown ultracentrifuge. No doubt in the next edition there will be much to be added to this section when the instrument is more fully developed.

The optical methods described are largely those of classical physical chemistry, but a supplementary volume is promised to bring this part thoroughly up to date. Once again the problem of defining the bounds of a topic arises. Infra-red, Raman and X-ray methods are mentioned. This is really all that can be done. These subjects are highly specialized, and although it is desirable that an undergraduate should have some slight experimental acquaintance with them, a detailed knowledge is not necessary.

The chapter on thermionic valves is absolutely essential, and might well be considerably extended in order that those not very familiar with the subject might be shown how to utilize with confidence these extraordinarily useful devices. The dielectric behaviour of substances is described in sufficient detail. Electrochemistry gets its quota of pages, and the useful polarograph is described in detail. The final chapter on radioactivity is brief. Perhaps here, too, the right line to take would have been to deal with natural and artificial radioactive indicators, which are becoming of ever-increasing service in all the many branches of chemistry.

As will have been gathered from these remarks, this book is of so comprehensive a scope that it must find a place on the bookshelves not only of physical chemists, but also of those who make the slightest contact with this rather ill-defined branch of science. H. W. MELVILLE.

HEALTH AND OCCUPATION

Health in Relation to Occupation
By Dr. H. M. Vernon. (Oxford Medical Publications.) Pp. viii + 355. (London: Oxford University Press, 1939.) 15*s*.

THIS book contains a valuable summary of existing knowledge on the subject of which it treats, and gives pointers to many directions in which new information is required.

Dr. Vernon investigates the relative importance of the three main factors—heredity, occupation, and social environment—on which the health of the community depends, and comes to the conclusion that occupation, though important, is of far less account in controlling health than the other two factors.

Any attempt to isolate and investigate the three factors is found to be extremely difficult, since they are almost inextricably interlocked, variation in any one factor having as a rule an indirect effect on the others. For example, the direct effects of heredity on health are shown to be inconsiderable, while its indirect effects, operating through the strongly inherited faculty of intelligence, are important; for example, the intelligent man is usually able to avoid on his own initiative many of the occupational risks to which he is exposed, while he also tends to rise to a higher grade of occupation which, being better paid, is on the whole less likely to induce ill-health.

The relative importance of heredity and environment in their effects both on health and intelligence is discussed. Researches into the characteristics of various classes of twins are described, and show that the 'nature *v.* nurture' controversy is still an open one, some investigators attributing to heredity only one half of the difference in *I.Q.* of children of the same parents reared together, others, after a study of numerous pairs of twins, making heredity three to five times more significant than environment. Perhaps it is true, as is asserted by one group of investigators of nineteen cases of identical twins reared apart, that "for twins reared together most of the differences between members of a pair may be due to the nature factor; whereas for twins reared under strikingly different environments the nurture factors will have a relatively greater influence".

Of the environmental factors which influence health, nutrition is shown to be by far the most important. Adequate nutrition is largely, though not entirely, dependent on adequate wages, which in its turn is dependent on economic causes of a controversial and complex nature. The writer reviews the problem of the nutritional standards necessary at all ages and under varying conditions of occupation; and shows that many 'protective' foods which should be included in a diet are beyond the resources of the worst paid members of the community. The ill effects of inadequate nutrition, particularly on expectant and nursing mothers, are described, and the beneficial results of certain controlled experiments examined.

In a survey of the present standard of living we find that recent investigations into the family income of working-class homes in London show that a third of them failed to reach the standard laid down by the author, while many were far below it. Wages form, in fact, the fundamental basis on which the adequacy of social environment depends; and Dr. Vernon states his belief that the greatest single factor for the improvement of the nation's health is the provision of an adequate income for all members of society.

Coming to the occupational factor, we find that, while a good deal is known about the effect of occupational conditions on mortality, we have little exact information as to their influence on health and sickness. The causes and effects of all known occupational diseases, as well as of accidents and psychological disorders, are discussed, and remedial measures suggested. But we are led to the conclusion that occupation acts on health more in an indirect manner by determining wages, and therefore social environment, than by any direct action.

Allowing for the effects of intelligence in increasing the importance of the hereditary factor, Dr. Vernon hazards the suggestion that the relative importance of the three factors may be estimated as: heredity, 40 per cent; occupation (direct effects), 10–20 per cent; and social environment, 40–50 per cent. He gives these figures as provisional, and as a challenge to criticism and a stimulus to the search for further much-needed information.

In his concluding chapter the writer discusses possible curative measures for the improvement of social conditions, and refers to plans which have been suggested by various authorities for a thorough-going revision of the health services of the nation.

May Smith.

INFORMATION AND PROGRESS IN ENGINEERING AND INDUSTRY

Records and Research in Engineering and Industrial Science

A Guide to the Production, Extraction, Integrating, Storekeeping, Circulation and Translation of Technical Knowledge. By Dr. J. Edwin Holmstrom. Pp. xii+302. (London: Chapman and Hall, Ltd., 1940.) 15*s.* net.

THE present work is a treatise on the collection and selection of information for use in the development of engineering and manufacture. Since progress in science and industry consists in the application of knowledge previously acquired, the problem of making this knowledge available in the fullest degree is a study of fundamental importance. Yet, for some reason, difficult to imagine, the laboratory worker, reading a gauge or shaking and looking at a test tube, enjoys support and prestige denied to the documentalist, engaged in processing the raw material of knowledge so obtained. Through such neglect, untold sums are wasted annually in working out engineering projects, developing inventions and conducting experimental researches which might have been saved altogether or begun from a more advanced starting point if the technique of finding out what other workers had already placed on record had been properly understood. Haphazard reading of the current issues of a few technical periodicals in moderation is not a waste of time. But, when we realize the thousands of journals, any volume of which, past or current, might contain information on a single subject, the method is seen to be essentially inefficient as a means of gathering specific information. Valuable time must not be frittered away in reading documents which are not the best for the immediate purpose.

The task of documentation is to provide a subject index that will enable us to select at will, from the millions of scientific and technical writings poured out, the particular documents relative to a specific inquiry. A single adventure in modern industry may depend for its realization on the application of the widest range of scientific and technical knowledge. Documentation needs to be organized from the point of view of science as a whole, instead of being worked in watertight compartments as at present, with a corresponding loss of efficiency.

Following useful chapters, describing in detail the present fortuitous concourse of research institutions, and the heterogeneous aggregate of "collative organisations", as the author terms them, the work passes on to discuss, in two important chapters, the methods of gathering ideas from technical literature and of sorting and integrating these ideas. The writer shows how the co-ordination of the mass of current unrelated abstracting and indexing work is being achieved gradually by the extension of the use of a standard method of classifying references. This method is the Universal Decimal Classification. Incidentally, it may be remarked that between a third and a half of the different items in scientific and technical literature indexed are now being classified by the standard method. In the Science Library at South Kensington, all references and abstracts classified in this way are cut up, mounted on cards and amalgamated in a central index of two and a half million cards, which is growing at the rate of from 120,000 to 150,000 cards annually. From this index, supplemented with a general collection of bibliographies and lists of references on all branches of science, comprehensive bibliographies on sufficiently restricted subjects of inquiry are prepared, free of charge, by an expert staff.

The book includes a description of the Kaiser System of indexing, for non-co-operative purposes, and gives due weight to economic and commercial aspects. The work appears at an opportune time, when the achievement of the greatest efficiency in documentation is essential. As an analysis of the subject and a comprehensive guide to sources of information, the volume should be in the hands of the business man, engineer, abstractor, indexer, and librarian alike.

S. C. Bradford.

JUNGLE PEOPLE OF TRAVANCORE

The Travancore Tribes and Castes

By L. A. Krishna Iyer. Vol. 2. Pp. liv + 344 + 86 plates. (Trivandrum: Government Press, 1939.)

MR. KRISHNA IYER is much to be congratulated on his lucid description of the history, customs and ceremonies of the tribes of Travancore. The careful classification of subjects makes the book of practical reference. In every way he tries to tell us the reasons and underlying ideas for the behaviour of these jungle people, all of which makes for greater interest. Each tribe section is preceded by a map showing the geographical distribution, an original and helpful arrangement. Many photographs of groups and heads aid description, and at the end of the book notes on index and stature are given. The volume is enhanced and framed as it were by an introduction written by Baron von Eickstedt, a masterly exposition of the development of Indian anthropology, and how the great Indian races have been studied, named and classified.

The ruling house of Travancore, seconded by Cochin, takes more interest in its aboriginals than any other State. They are treated as a 'backwards community' and helped in every possible way; if necessary by giving land and establishing small colonies. Travancore was our first ally to establish law and order in India in the days of Tipoo Sultan, and it is interesting to note that in 1812, the Maharani of Travancore abolished slavery entirely in her realm, anticipating the British Government in this much-needed reform. In the chapter on the Pulayas (who were originally slaves and look it) there is most interesting reading on this subject (pp. 121–129).

The historic and amazing proclamation by the present Maharaja on the right of temple entry (1936) astonished all India. It will go down to posterity as a charter of religious liberty, says Mr. Krishna Iyer (p. 129).

The author begins this volume with the Muthuvans, a most intriguing people with an aquiline nose peculiar to them. The tribe are accomplished hill men though they came from the plains. The region which is now their habitat has the most entrancing scenery of all Travancore. Their method of cultivation can be seen from any hill top, for they make clearings in the jungle like all primitives, believing that mother earth should not be slaughtered with a plough. When they have made seven 'kudis' they go back to No. 1. Their women are never or rarely seen. I believe I was the first European to be allowed to meet some and photograph them. From shyness or custom they hide in the jungle at the approach of a stranger.

There are many interesting pages about their form of worship, which is a complete mixture of Hinduism and animism (pp. 28–33). I was taken to see just such a temple to Subramani as the one described. The Muthuvans worship the sun both morning and evening. "O God we live in the jungle. We are ignorant of everything. Protect us". It is probable that this worship may at one time have formed a prominent part of their religion. Their prayers are always naïve and direct: "O God save us from elephants, pigs and panthers". "O God, my cultivation is being ruined for want of rain. It would be a good thing if it rained". There is much charm, too, in their folk-lore: "Earthquake is believed to be caused when the goddess removes the earth from one shoulder to the other because of its weight".

Palayans and Uralies are only to be found around Periyar Lake, another beauty spot in Travancore (pp. 68 and 223). Here big game can be hunted as well as tribes, for there is a five-mile preserve round the Lake. Bison and elephant come there regularly to drink; a tiger walked across my track while I was visiting a Palayan village. These isolated groups of people are extraordinarily brave. The Palayans welcomed me in a most original way; they had built a bench with a decorated canopy over it to give me shade, and their manners were charming.

Nothing more picturesque can be imagined than an Uralie hamlet; they build most of their huts in the trees, for like the Muthuvans they live in daily terror of elephant, which trample and eat up their scanty crop. Shooting wild elephant is made difficult in Travancore, for the legend runs that when elephants disappear the line of Maharajas will also cease.

The Uralie marriage laws are unique. "No man can have a wife unless he has a sister whom he can give in exchange." So far as I could discover, the unfortunate sister is left at the bride's house and has to act as daughter there (p. 229).

Mr. Krishna Iyer tells us much that is of interest about the Nayadis, a remnant of an ancient people (p. 49). Those of Cochin State are short of stature and miserable looking, and they spend their day in begging in the bazaars. Possibly even these will be reformed and civilized by a patient Government. A reform of this kind will cause no sorrow, but anything that tends to change the native dress and customs of these ancient and wonderful tribes saddens me, and I look at the photograph of the Thanta-Pulayas in their leaf garments on p. 123 with regret.

MARGUERITE MILWARD.

TREATMENT OF ABATTOIR WASTES

By J. H. Codling, M.B.E.,

City of Birmingham Salvage Department

THE products obtained from the treatment of abattoir wastes are progressively assuming greater importance in our war-time national economy. For many years several of our larger municipalities have recognized the potential value of these wastes and have acted accordingly, but there are still many authorities which even now ignore the important contribution which these wastes can be made to pay to our war effort. The reason in many cases may lie in the fact that apparently the amount of such waste is too small to warrant the installation of plant for its treatment; perhaps in other cases it is imagined that insuperable technical difficulties will beset the path.

Nature and Classes of Raw Materials

The slaughterhouse wastes usually available for treatment by municipal authorities consist of condemned meat, and the viscera consisting of the intestines, stomachs and other organs of slaughtered beasts. To this may be added, whilst not strictly abattoir waste, such materials as fish and fish offal waste. From such crude raw materials, after suitable processing, there are produced feeding meals for pigs and poultry, organic fertilizers of first-class quality, and incidental to the process there results the reclamation of the valuable fat content of the tissues which to-day is of such importance in the manufacture of explosives. Household bones recovered from house refuse may similarly be treated for the production of a fertilizer or a feeding bone meal and the recovery of bone fat.

Referring to my own experience in Birmingham, where a process known as 'Dry Rendering' is in operation, and to which the ensuing facts relate, we treat here about 5,000 tons annually of such raw materials as are included above, and produce therefrom about 1,000 tons of fertilizers or feeding stuffs and about 200 tons of fat. As glue is a material of such great importance in aeroplane manufacture, all the bones recovered from the house refuse of Birmingham are sold to firms which specialize in glue recovery; these firms simultaneously recover the grease, and the meal residue is a bone fertilizer. Otherwise, if treated, as they can be, through the ordinary process of rendering, the glue would not be recovered but left in the meal as the protein content, in which form, of course, it still serves a valuable purpose used either as a feeding meal or fertilizer. If glue recovery were desired, it would mean setting up special digestors and other plant to deal with what is, after all, only a relatively small proportion of our raw material.

Derived Products

Condemned meat is a valuable raw material, yielding as it does a valuable meat meal for feeding purposes, and fat. The carcasses are treated as received, the only preliminary treatment being the cutting up into suitable sizes for feeding into the machines employed in their processing. In round figures this material yields about 25 per cent of feeding meal and about 15 per cent fat. Again in round figures, the feeding meal, which is dried down to about 10 per cent moisture, shows on analysis about 55 per cent protein, 10 per cent oil and 9 per cent phosphoric acid. It is obvious, therefore, that this product is a highly concentrated food; it is sweet and palatable, completely sterilized, and is worth to-day about £15 per ton.

Slaughterhouse offals, consisting of ropes (intestines), farthings (stomachs), paunches and various other organs are all treated together with their ingesta for the production of a fertilizer, and the recovery of their all valuable gut tallow. Incidentally, this tallow is coloured green, due to the chlorophyll present in the food which the beast has eaten, but it is none the worse for this as the fat refiner easily bleaches it. About 20 per cent yield of fertilizer is obtained, which apart from the value displayed by its analysis has the further advantage of a high content of humus-forming material; also about 5 per cent fat is obtained. The fertilizer, dried down to about 10 per cent moisture, shows between 5 and 6 per cent nitrogen and about 3 per cent phosphoric acid; it sells at about £5 per ton. In the Birmingham process we have found it better to let the white fat recovered from condemned meat run to the same tank as the green fat from the slaughterhouse offal rather than make two fat products, although this can be done if desired.

Fish, if white, is worth treating separately from the oily fish, and can then be used as a fish feeding meal, whilst usually the product of the oily fish, after oil extraction or even without, is used as a fish manure. If the respective quantities available do not warrant separate treatment, then the whole of the fish waste is converted into a fertilizer. About 25 per cent recovery is effected and the manure will analyse 8 per cent nitrogen and 8 per cent phosphoric acid ; its value to-day is between £10 and £11 per ton.

In the case of small towns the initial segregation of the raw material into such classes as the above may not be warranted owing to the small quantities respectively available. Under such conditions the procedure of treating the whole of the raw material together for the production of fertilizer and fat is successfully practised.

PLANT AND PROCESSING

The raw material to be dealt with contains some 70–80 per cent moisture, and it is the purpose of the process to reduce this to about 10 per cent, in which condition, suitably stored, the resultant meal will keep for an indefinite period. In addition it is obviously desirable to remove as much grease as possible from the tissues. The type of plant which I consider most suitable for the use of municipalities is that known as Dry Rendering, which is the one I propose to describe.

The drying process is effected in a cylindrical steam-jacketed vessel lying horizontally (Fig. 1). This vessel is fitted with revolving arms driven by a motor which keep the contents of the vessel agitated to assist the free emission of the water vapour during the drying process. A charging hopper for the introduction of the raw material is fitted to the top and a discharging door for the removal of the finished product is fitted to one end. These machines are built in various sizes and designed to suit whatever steam pressure it is desired to employ in the jacket.

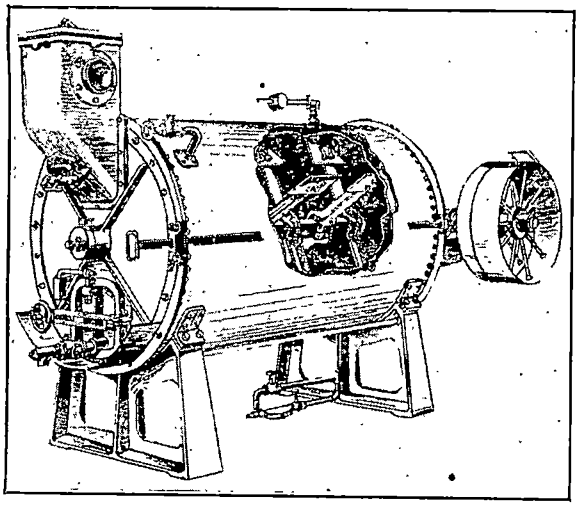

Fig. 1

DRAWING OF DRYER WITH SIDE CUT AWAY TO SHOW AGITATOR INSIDE AND STEAM JACKET. CHARGING HOPPER AND DISCHARGING DOOR ARE AT FRONT OF MACHINE.

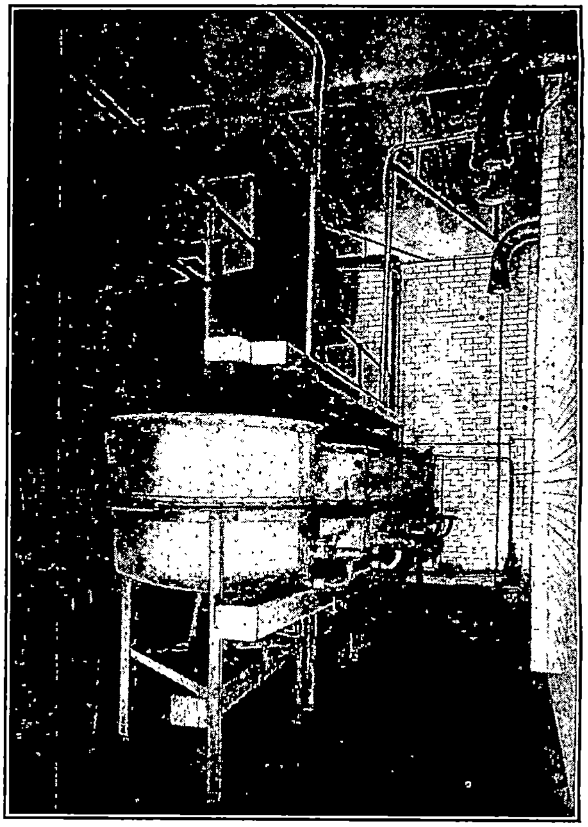

Fig. 2

FAT-CLARIFYING TANKS. FAT EXTRACTORS ON FLOOR ABOVE DISCHARGE INTO THESE TANKS THROUGH THE VERTICAL PIPES.

The fat extraction is usually effected at the conclusion of the drying process by subjecting the hot greasy product from the dryer to pressure. The machine employed is known as a Turbine Centrifugal Fat Extractor. It consists of an outer steel cylindrical case containing a rotor which is caused to revolve by a steam turbine in the base of the machine. A cylindrical perforated steel cage, fitted with a filter cloth, is loaded with the material to be fat extracted and then lowered into the rotor by a hoist. The lid of the machine is closed and steam turned on, which causes the rotor to revolve. The steel cage and its contents are thus caused to revolve at 650 r.p.m., and this revolution gives rise to centrifugal force which results in the contents of the cage being pressed up tightly against its side. The great pressure exerted squeezes out the fat, which passes through the filter cloth—the latter retaining the solids—and so to the fat purifying tank. This fat extraction usually takes forty minutes for a charge of 4–5 cwt. of material, and properly effected will leave only some 10 per cent fat in the finished product. After fat extraction the machine is stopped, the cage removed and its fat-extracted contents tipped out. This product is cooled and then ground down through a disintegrator into a uniform finely divided meal, in which form it is bagged and sold. The fat recovered passes by pipe-line from the extractor to a fat purifying tank which is fitted with a steam coil. Here water is added and brought to the boiling point by the steam coil, whilst the fat is agitated. After this washing, the contents of the warm tank are allowed to settle. The impurities sink to the bottom and are finally run off with the wash water, after which the fat is barrelled ready for sale (Fig. 2).

Briefly, therefore, the procedure is to charge a dryer with the appropriate quantity of raw material. The machine is closed, steam turned into the jacket and the agitator set in motion. After 5–6 hours the machine is stopped and its contents discharged. If oil extraction is to be undertaken, they are discharged into a suitable tank from which the fat extractor cage is filled. The latter is placed in the fat extractor and set in revolution and subjected to centrifugal pressure for forty minutes. The machine is stopped, the cage removed, and its contents discharged; they are then cooled, ground down and bagged. The extracted oil is clarified and barrelled, as already described.

In the confines of this brief article no more than an outline of the process can be attempted. In passing, however, mention should certainly be made of a rather more elaborate dryer, known as the Iwel Laabs, which is a machine possessing certain advantages not the least of which is that it definitely secures complete sterilization of the product, whilst its operation is but little less simple than its prototype described above.

CONTROL OF FOUL VAPOURS

It is obvious from the very fact that the raw material is 'waste' that much of it will be in a more or less decomposed state, and the vaporous products of this decomposition can be decidedly unpleasant. During the drying operation these vapours are driven off with the water vapour, and unless precautions are taken an atmospheric nuisance will arise. Fortunately the bulk of these vapours are soluble in water, so that the vapours emitted from the dryer are passed into a condenser where they meet a spray of water which affects their solution, and this is run off to the sewer. The uncondensable portion of the vapours will, however, pass out of the condenser, and these vapours must be carried to some point and destroyed. This can be effected by passing them into a region where a continuous and uniform temperature of 1400°–1500° F. can be maintained.

But the more effective modern method is to subject these uncondensable vapours to the action of chlorine, whereby they are completely oxidized and rendered odourless. The apparatus to effect this desirable metamorphosis is cheap initially and in upkeep, and low on its operation charges. The chlorine is purchased as a liquid gas in cylinders and connected to suitable apparatus known as a Chloronome, which measures out and applies the correct dosage of chlorine to the vapours being treated. As the uncondensable vapours leave the condenser the correct dose of chlorine is injected into the pipe conveying them, and means adopted for securing intimate admixture. The result may be discharged direct to atmosphere in an odourless condition. In the plant under my control, four machines simultaneously emitting their maximum quantity of vapour require only 1/10 lb. of chlorine per hour for its deodorization. The use of chlorine gas implies corrosion of the metals with which it comes in contact. Suitable precautions, such as painting all exposed surfaces with heavy coats of bitumen, must therefore be adopted.

PLANT REQUIRED

The amount of plant required is, of course, intimately related to the amount of material it is proposed to treat and the size of the machines it is convenient to purchase. Hence no advice can be given on this matter. The only guidance one can provide is that a small 7 ft. dryer, two small turbine extractors or one large one, a fat clarifying tank and a small disintegrator should be capable of treating 10 tons of raw material per week working a twelve-hour day. Complete guidance on this matter can, however, always be secured by laying the full facts before manufacturers of the plant, such as the Industrial Waste Eliminators, Ltd., of London.

I know that some authorities have been deterred from undertaking this work, due to the fact that they consider there is insufficient raw material available in their area to warrant the installation of the necessary plant. I am informed, however, that a plant laid down to treat only three tons of raw material per week is making a satisfactory return. Generally, this amount can be easily exceeded, especially if a few small neighbouring authorities co-operate in the disposal of this waste.

Power and Steam Requirements

The power and steam requirements of the plant employed are again regulated by its size and the amount of work undertaken. Obviously, however, such a plant can make very effective use of the steam produced, say at a refuse disposal works, from the burning of house refuse.

As some guidance in the matter, a moderate-sized plant would require the following power supply:

Dryers. 4–5 units per 1,000 lb. of raw material treated.

Disintegrator. About 20 units per ton per hour.

The steam consumption of the same plant would approximate to the following:

Dryers. 870 lb. per 1,000 lb. raw material treated.

Vacuum pump. 85 lb. per 1,000 lb. raw material treated.

Fat extractor. 140 lb. per 1,000 lb. raw material treated.

Fat clarification. 500 lb. per ton of fat clarified.

The adequate supply of feeding stuffs and fertilizers is rapidly becoming an increasingly important factor of our national economy and it behoves everyone in a position to do so, to examine the possibilities of what contribution can be made on the lines indicated above. Even if such raw materials as specified are unobtainable, there is still the problem of converting kitchen wastes into dried pig and poultry meals, which can be solved on similar lines and with the same plant, except that fat extraction will be unnecessary.

GEOLOGY AND EARLY MAN: I

By T. T. Paterson,

University Museum of Archæology and Ethnology, Cambridge

THE postulates summarized in this, and Part II, are the results of work on five expeditions, two to the Arctic with the Wordie Arctic Expeditions, to India and the Himalaya (Yale-Cambridge Expedition 1935), to East Africa, and to Northern Europe. I was financially assisted by Trinity College, Cambridge, the Royal Society, the Percy Sladen Fund Trustees, the Royal Geographical Society and Mr. L. C. G. Clarke, and have been in receipt of a senior studentship from the Commissioners of the 1851 Exhibition.

A System of Pleistocene Correlation

The correlation of the various phases of the Pleistocene throughout the world has not been in any way assisted by the obscurities attached to the interpretation of 'pluvial periods' within the non-glaciated regions. Nor has the palæontologist been able to supply enough fossils and variations of types which could give the necessary detail, one point only being of outstanding value, the palæontologist's view that the commencement of the Pleistocene is marked by the appearance of Elephas, Equus, and bison, or any one of these. This definition of Haug was adopted by James Geikie in his, the first, Pleistocene correlation system, and is followed here, as well as Geikie's simple nomenclature for glacial periods. It is deplorable that Geikie's work (which not only takes priority but also has not been seriously challenged), has been discarded in favour of a nomenclature having purely a local application to the Northern Alps. The chief sinners in this respect have been prehistorians, but lately the disease has spread among geologists and has been furthered by writings which not only show complete lack of appreciation of the works of the master but also introduce new Continental expressions into our nomenclature where plain English has well sufficed before.

A new approach is necessary, and it seems that a solution lies in the recognition of a world-wide system of three easily recognizable major cycles of sedimentation, each beginning with a coarse and ending with a fine facies. The beginning of the first seems to coincide nearly uniformly with the known earliest occurrences of the Pleistocene faunal group of Haug. These cycles are here named the Lower, Middle and Upper Pleistocene. The accompanying table illustrates the system and is self-explanatory. Each major cycle shows a subdivision into subsidiary cycles when a rejuvenation of sedimentation marks out the Lower into two phases l_1 and l_2, the Middle into m_1 and m_2, and the Upper into u_1, u_2 and u_3. Within the glaciated regions the commencements of each of the major cycles coincide with Geikie's first three cold periods, the fourth cold period marks the beginning of phase u_3, and the fifth the end of the Pleistocene.*

---

E = erosion. Detached Arabic numerals to right of columns represent glaciations, Geikie nomenclature. M = earth movement.

A SYSTEM OF PLEISTOCENE CORRELATION.

Within the non-glaciated regions, the beginning of each of the seven phases is marked by an erosional disconformity which, if it is thought essential, could be interpreted as evidence for a 'pluvial period'. The major periods of aggradation (see curve) follow on those erosional periods coincident with glacial advance, and end in stages of stability prior to the rejuvenations of erosion marking the next, subsidiary, phases. The first three erosional periods can only be observed as stratigraphical disconformities in section, but the last five are very widely met with as terrace escarpments. The method adopted here of defining terrace forms by the erosional scarps which isolate them has been found more satisfactory and less liable to misinterpretation than classification on terrace components which are often composite. The five terrace escarpments are named T_1 to T_5 and the top surface of deposition—aggradation gravels of m_1 succeeding the big second glaciation—T_D.

The first two cycles end with episodes of aridity which, in the tropical regions, may occupy almost the whole of the 'rejuvenation subsidiary' phases, l_2 and m_2. Dry episodes occur also at the ends of phases u_1 and u_2. In periglacial regions such arid episodes are represented by loessic deposits, in sub-tropical parts by æolian silts, and in tropical regions by bands of rock, shattered by insolation and brought to level by solifluxion during the short, but intense rainy seasons.

Under the heading 'Geikie system' the curve represents climatic change within the glaciated regions, the middle interrupted line indicating temperate climate, and curves to the left and right indicating warm and cold respectively, the depths of the glacial maxima, 1 to 5, showing ice sheet extensions rather than actual climatic extremes, for the fourth ice advance was the coldest. The repetitive cyclic character of the curves of climatic change and sedimentation variation will be seen to correspond. So it seems that the greatest ice extension and locking-up of water coincided with the greatest erosional activity in most parts of the Old World, that is, with increase in precipitation there. Therefore the factor of eustatic variation must be taken into account as important when considering the relations of base level change and isostatic compensation for ice load. The question of precipitational change will be looked into in the next section.

One further point emerges. At the beginning of both the Middle and Upper Pleistocene, there was earth movement of some kind in all except the most stable crustal blocks. In an orogenic region there may have been even over-folding and thrusting as well as uplift. For example, in the foothills of the Himalaya the Lower Pleistocene (Upper Siwaliks) were thrusted, and uplift of 6,000 ft. has taken place since the beginning of Middle Pleistocene times. At the opening of the Upper Pleistocene there was no folding, but warping began and has gone on even to the present day. In a region of rifting, faulting occurred accompanied by volcanic activity, as for example in the Rift Valley in East Africa. In the stable areas of South India and South Africa there is little evidence for earth movement, but in the Scandinavian and Canadian shield areas there are indications of vertical crustal deformation. In south Britain this was of the order of several hundred feet where, also, the London Basin was further warped on its northern flank. In the eastern Asiatic periphery and in the Rift Valley the tectonic activity of the beginning of Middle Pleistocene times extended the erosional disconformity into unconformity.

The faunal variations cannot be given here owing to lack of space, but in general it can be said that the Villefranchian type of assemblage is confined to the Lower Pleistocene, with some Pliocene survivals into phase m_1 as at Mauer and in China. By phase m_2 Pliocene survivals have gone, but the characteristic Upper Pleistocene forms, as for example *Elephas primigenius* and *Bos primigenius*, have not appeared. It seems that the intensity of cold in the fourth glaciation and the aridity which preceded and succeeded it in the later parts of the Upper Pleistocene were the causes finally of the disappearance of the Pleistocene fauna.

The close relationship of human cultures to the geological sequence is described later.

CAUSE OF THE ICE AGE

The cyclical character of the glacial and sedimentary curves and their correspondence has been remarked upon. It seems, therefore, that all over the world there has been a coincident series of changes in precipitation. Moreover, the curves show a progressive decrease in 'swing'; that is, the cycle of change decreases in amplitude from the beginning of Middle Pleistocene times onwards. A glance at any set of terraces would be convincing enough on this point. This decrease in amplitude is essentially a curve of recovery, the first stages in the Lower Pleistocene being the shorter 'build-up' towards the maximum, and the later stages the longer recovery. Obviously the catastrophe from which recovery has taken place must have occurred in Tertiary times.

In the north, in Scotland, Scandinavia, Greenland and Arctic Canada, a consistent set of physiographical features can be seen. A high-level plateau surface of mature form is surmounted by monadnocks which have undergone the effects of extreme frost-shattering and are now sharply

'Alpine' in appearance. Cut out of this old land surface are deep steep-walled canyons and fjords, which follow lines of weakness determined by major joint planes, and often, therefore, show a cruciform appearance. In both Baffin Land and Norway the fjords obviously constitute entrenched drainage systems cutting through ranges of uplifted mountains, for example, the Sogne Fjord. The matured plateau form slopes away on either side of this backbone, hence the fjord system has cut back and captured on the inner side of the range. This is well shown by the run of obsequent forms near the head waters of some of the main fjords which have so cut back. Where the system is merely entrenched into the older plateau form, which is the most common type in Norway, the heads of the fjords are very steeply graded. Further signs of rapidity of entrenchment is the presence of dry valleys—steep-walled, fjord-like in character—which have been partly cut during first stages of erosion, and left dry when the eroding stream was diverted by capture into the deeper main fjords. This is a well-marked phenomenon in eastern Baffin Land and also occurs, though sparsely, all over western Norway and in Scotland too.

That these fjords were due to the action of fluviatile, sub-aerial, erosion is demonstrated not only by the above evidence but also by V-shaped forms of the wider valleys, truncated spurs and, quite often, the serial right-angled bends in the courses of the fjords due to the intersection of major joint structures. The erosive power of ice in such valleys must have been greatly reduced. The V-shaped forms nevertheless show oversteepening due to glacial action. The valley sides in the upper parts of the fjords have composite profiles, for erosion during interglacial periods was apparently as strenuous (measured in depth) as that during glacial, and the result is a succession of V- interrupted by U-forms.

Corresponding to these older glaciated profiles are a series of three cirque types—old, mature, and young—which seem to correspond to the first two, the third, and the fourth glacial stages respectively. The terraces within the fjords are associated with the third, fourth and fifth glacial advances (and their substages) and with post-Pleistocene oscillations. The old cirques in the main fjords come well down to present sea-level, and are occasionally even drowned. The skjaergard is cut out of it and itself glaciated, and is thus Middle Pleistocene in age. Finally, the fjords are cut out of Tertiary rocks in Greenland and Canada; therefore the fjords must be, at the oldest, of late Tertiary age.

As a whole the evidence shows that during the latter period there was widespread uplift, in places over 4,000 feet, of a block comprising the Scandinavian Shield, Greenland and the northern part of the Canadian Shield, the result of the great Tertiary tectonic activity. Simultaneously, the poles shifted. The North Pole, in early Tertiary times situated in the north Pacific, moved towards its present position; that is, the poles became coincident with the newly uplifted block in the north, and the antarctic continent in the south.

Furthermore, it seems that precipitation increased, for it is unlikely that the rivers which established the mature Tertiary landscape would have been able to erode the incised fjord system. To account for this increase of precipitation, it is suggested empirically that polar shift and crustal deformation led to such a variation in geography that the precipitational norm had to be adjusted. The matter still awaits mathematical treatment. Given these conditions, it will be seen that the explanation of glacial and interglacial periods can be achieved by application either of Simpson's theory or of Croll's radiation curve. On broad grounds it appears to me that Simpson's theory fits the facts on a wide basis, accounting for the precipitational changes in other parts as well as glaciated regions.

After uplift, recovery: the land subsided and the fjord systems were drowned. The deep valleys incised into the continental shelf during the period of exposure were drowned and became submarine canyons. Later, ice sheets filled these canyons near the ice peripheries with detritus. Decreasing compensatory oscillations proceeded well into the Pleistocene and were materially affected by secondary factors such as ice load. As glaciation lagged behind uplift, so the glacial and sedimentary curves of recovery lagged behind the curve of isostatic recovery. The coincidence of crustal deformations over wide areas is significant, and one suggestion may be hazarded here. The last expedition led by Col. Seymour Sewell to the Indian Ocean demonstrated the existence of a submerged rift feature the mirror image of the African Rift Valley. The major part of the rifting occurred in late Tertiary times, that is, when uplift occurred in the northern hemisphere. (Somewhat similar uplift occurred in the south, as witnessed by the physiography of New Zealand and South America.) Bullard has demonstrated that the rifting is due to pressure, not tension. The two regional adjustments may be intimately related, for crustal pull at the poles will produce longitudinal shrinking and therefore pressure at the equator. This same shrinking may take the form of crustal drift (and hence orogenic movement) in a direction at right angles to the shrinking. Thus would occur mountain-building movements in an east–west direction, the Himalaya, the Caucasus, the Alps.

(To be continued)

M. V. LOMONOSOV (1711-1765)*

By Prof. J. D. Bernal, F.R.S.

THERE are few names in the history of science that have been more strangely passed over than that of Mikhail Vasilyevich Lomonosov. Because his life was spent for the most part beyond the confines of the scientific world of the eighteenth century, his ideas and his influence never made themselves felt outside Russia, but there he is revered as the real founder of Russian science with as just a title as Liebniz in Germany, or Franklin in the United States.

No one could have excelled him in his determination to pursue and develop science. He was born the son of a poor fisherman on a remote island on the fringe of the Arctic Circle. Although Russia was then, apart from the newly formed capital of Peter the Great, sunk in complete barbarism and ignorance, he forced his way to knowledge. At the age of nineteen he went to Moscow, where, passing as a priest's son, he managed to enter a monastery school which could teach him little but Latin and church Slavonic. Three years later he was called among the most gifted pupils to the newly formed Academy at St. Petersburg, at this time an entirely foreign creation. The Government wanted to train native Russians in prospecting the great mineral resources of the country and in setting up new industries. Lomonosov was one of three who were sent abroad for this purpose. He studied mining at Freiburg, and general science under the great Christian Wolff at Marburg. There at last he came into contact with the full stream of eighteenth century scientific enlightenment, and when he went back to Russia four years later he was able far more effectively than his foreign colleagues to introduce that spirit into his country.

It would have been remarkable enough if Lomonosov had acted as an apostle of scientific culture in Russia, but he was far more than that. Brought up out of contact with the whole tradition of the West, he was, after a few years' study, able to grasp it and in a large measure to transcend it. Possibly because of his very freedom from preconceived ideas, his work shows him to have possessed a clear comprehension of physical and chemical principles a century before they won general recognition. Lomonosov's writings are few, and mostly buried in the archives of the St. Petersburg Academy, but each one of them is an expression in the most orderly and clear way of some fundamental principle in physics or chemistry.

In a century when chemical theory was deeply buried in confused mysticism, Lomonosov introduced clear and precise terms. In his "Elements of Mathematical Chemistry" in 1741, he gives definitions of elements, compounds and molecules which would pass muster to-day. Even more surprising was his description of the structure of solids, liquids and gases, and his first statement of the mechanical theory of heat and the kinetic theory of gases, leading him, in particular, to postulate the existence of an absolute zero. His analytical mind refused to deal with such concepts as phlogiston or fiery principles; to him the increase in weight of metals on calcination was due to the combination of atoms from the air which could be expelled on further heating. But lacking the devices of pneumatic chemistry, he was unable to anticipate the discoveries of Priestley.

In physics, Lomonosov's chief contribution was to meteorology (where he devised an anemometer) and atmospheric electricity. His colleague Richter was the first victim to the study of lightning that Franklin had started. Lomonosov speculated acutely on the causes of the aurora and the importance of cold fronts in weather changes. Perhaps more remarkable than any individual achievement is the way in which Lomonosov understood the nature of systematic scientific inquiry. This is shown very clearly in his lectures on "Real Physical Chemistry" in 1752. He is particularly insistent on the need for quantitative methods in chemistry, and for the measurement of all physical properties connected with chemical reactions. Of the relations between physics and chemistry he wrote: "A physicist without mathematics is blind, without chemistry he is paralysed". His understanding is shown best by his research programmes, which he initiated and carried out in the new University of Moscow, of which he was the founder and first principal. Unfortunately the note-books containing his results have been lost, but the programme of the work shows its comprehensiveness. On the solution of salts, for example, he proposes to measure:

(1) The solubility of all principal salts at different temperatures.
(2) Density of different solutions.
(3) The change in volume on solution.

---

* Substance of a lecture delivered on June 28, under the auspices of the Society for Cultural Relations between the Peoples of the British Commonwealth and the U.S.S.R.

(4) Change in temperature on solution.
(5) Variation of the density with temperature, to the freezing point.
(6) Effect of solution on the boiling point.
(7) Specific heat of the solution.
(8) Mutual effect of different salts on each other's solubility.
(9) Rate of freezing.
(10) Effect of dissolved air.
(11) Whether solutions self-cooled regain heat as rapidly as those cooled externally.
(12) Effect on cohesion.
(13) Refractive indexes of solutions.
(14) Capillary constants of solutions.
(15) Microscopic examination.
(16) Effects of pressure in a Papin's digestor.
(17) Effect of an electric field.
(18) The colour of electric sparks and arcs in solutions.
(19) Comparison of solutions in vacuum and in air.

We are still trying to complete the programme he here sets out, but its recitation is enough to show what an extremely modern view he held in physical chemistry.

The distinctive character of Lomonosov's work was that he combined the mathematical inheritance of the Newtonian era, which he no doubt derived in the first place from his master and friend Euler, with an extremely lively and detailed interest in the actual phenomena of Nature and in the practices of the arts. We can recognize now a general relative decadence of science in the middle of the eighteenth century, a turn to formal mathematics and experimental dilettantism. Lomonosov stands out against this background, and foreshadowed the great work of the period of the French Revolution. He resembled Lavoisier in his mental approach to the problems of chemistry. His curiosity, though insatiable, was ordered and practical, and he was an organizer of research as much as a thinker.

Here we have a scientist of the first rank, but Lomonosov was a great deal more than that. His most important immediate influence was in quite a different sphere, that of philology and poetry. He is still revered as the first native Russian poet, and Pushkin repeatedly acknowledged his debt to him. He wrote the first Russian grammar as well as the first modern Russian history. All through his life he struggled against the cramping influence of the traditional and clerical obscurantism of old Russia and the trivial and pedantic atmosphere of the Court and the Academy. Unlike many more famous men he was never deceived by the flattery of the great, but worked steadily for the education of the Russian people.

How was it that with all his ability and achievement his work seems to have had so little immediate consequence in the world of science ? Partly no doubt because of the distance of Russia and the degree to which it was cut off from the active world of English, Dutch and French science ; partly because of the jealousies and vested interests of the foreign academicians ; but most of all it was due to the backwardness of life in Russia, of which Lomonosov himself was so well aware when he lamented that there was no one to understand him or to carry on his work. But Lomonosov's work did not go unrewarded, however little immediate influence it had in the West. It was to him that the great liberating influence of scientific thought in nineteenth century Russia was largely due. But it is only in the past twenty years that Lomonosov's aspirations have been realized. The Soviet Union is now celebrating his 175th anniversary; but it is the utilization of the resources of the country and the spreading of scientific education to all that marks the real culmination of his work.

OBITUARIES

Mr. O. Gatty and Mr. A. S. Chessum

OLIVER GATTY, who died on June 5 at the early age of thirty-two from an accident when engaged on research in the service of his country, was an investigator of exceptional calibre and promise and possessed a mind of unusual capability. From Winchester he went to Balliol College, Oxford, where he obtained a 'first' in chemistry in 1930. In 1931 he was elected to a tutorial fellowship at his College. His interests, however, were in research rather than in teaching, and two years later he resigned in order to visit Rothamsted, where he became interested in the mechanism of living processes. He left Rothamsted to work with Prof. J. Gray in the Department of Zoology at Cambridge, and later joined my Laboratory.

Gatty showed that all the phenomena such as passivity and corrosion attending the immersion of metals in solutions of electrolytes could be interpreted on the basis of local action currents involving the presence of anodic and cathodic areas. It was with this background that he approached the subject of biopotentials. He quickly realized that thin layers of insoluble substances could not affect the electric potential difference between two phases in equilibria, but that they might produce profound effects if there existed a diffusion potential between the two phases. These diffusion potentials are in all probability the result of continuous enzymitic processes. The ionic permeability of the thin interphase membrane thus becomes one of the important factors in the magnitude and sign of the biopotential. Gatty carried out a series of interesting experiments on frog skin, and showed that all the bio-electric phenomena observed with this material could be accounted for if the frog skin were regarded as electrically equivalent to a resistance in series with areas permeable to anions and cations respectively. He made the further tentative suggestion that the cathodic areas might be the pores between the cells.

Gatty could dissect a complex problem into its simpler components and bring to bear on each a mind possessing the unusual faculty of not only visualizing the mechanical nature of the problem, but also of combining with this mathematical analysis.

He was a man with wide interests, attending the Ottawa Conference in 1932, and was a member of the Spitsbergen Expedition of 1933. He was likewise deeply interested in psychic phenomena. His personal charm, his humour, and his unvarying kindness and sympathy for the underdog won him many friends, both in and outside the Laboratory. Although I knew Oliver Gatty for all too short a period, he was rapidly becoming one of my closest friends.

Eric K. Rideal.

Alfred Stanley Chessum was for thirteen years a member of the workshops staff of the Engineering Laboratory of the University of Cambridge. He was an exceptionally brilliant craftsman—a man endowed with ability to think round his work and capable of producing anything within the capacity of the plant entrusted to him.

These qualities singled him out, and consequently he was chosen to build the apparatus for Mr. Gatty's experiments. Chessum's enthusiasm for this work was possibly only excelled by that of Mr. Gatty himself, and many of Chessum's ideas were incorporated in the design. He understood the urgency of this problem and worked quickly to produce the apparatus in the shortest time. The tragic circumstances which ended this series of experiments have robbed this department of a pleasant and cheerful personality, and a man whose sound common sense and outstanding qualities must be considered irreplaceable.

C. E. Inglis.

Prof. J. H. Muirhead, F.B.A.

Prof. John Henry Muirhead, who died on May 24, carried his eighty-five years so lightly, his vigour of mind was until the last so abundant and his sympathy with young life and new ideas so unfailing, that it is hard to think of him as what he was, perhaps the last surviving representative of the Idealist philosophy that had its heyday in the eighteen-eighties and nineties. But as a pupil of Edward Caird in Glasgow and of T. H. Green at Balliol, he had been in the movement from its beginning and was to watch its extending influence far beyond the ranks of academic theory, then, in the last generation, its decline before the criticisms of younger movements. If not one of the leading thinkers of the school, Muirhead was certainly one of its most successful and indefatigable teachers, both directly for more than a generation in university posts and indirectly through his wide personal contacts, through his work for the British Institute of Philosophical Studies and in many other ways, while his writings cover a period of not far short of half a century. Finally, as a foreign critic has remarked (Dr. R. Metz, "A Hundred Years of British Philosophy"), Muirhead "made a distinguished contribution to the history of the idealistic movement. Placing it in a wider intellectual setting, he has sought to understand its origin and development as well as its total significance". The reference here is especially to his book on "The Platonic Tradition in Anglo-Saxon Philosophy" (1931).

Muirhead's own special interests were mainly in the bearing of philosophy upon human life and the social sciences. His first book, "The Elements of Ethics" (1892, fourth edition 1932), has for long been widely used as a text-book; he used to enjoy telling how some years ago it was banned in Japan because of a passage misinterpreted as putting forward a defence of tyrannicide. "Philosophy and Life and other Essays" (1902), "The Service of the State" (1908), "Social Purpose" (in collaboration with Sir H. J. W. Hetherington) (1918), "The Use of Philosophy" (1928), "Rule and End in Morals" (1932) are indicative of this primary interest, as is his last published work, the Herbert Spencer Lecture delivered at the University of Oxford less than two years ago on "The Man versus the State". His little book on "German Philosophy in Relation to the War", written in 1915, was a corrective to certain war-time prejudices for which there is again a use to-day.

As general editor of the series "Library of Philosophy" over a long period of years, Muirhead not only displayed his own catholicity of sympathy and interest in thought of widely different tendencies but was also instrumental in introducing to the English reader the works of eminent foreign and American thinkers such as Bergson, Croce, Varisco, Radhakrishnan. He was also general editor of a valuable collection of personal and autobiographical statements "Contemporary British Philosophy" (1924-25). Up to the end of his life he always delighted in opportunities to hear from practising men of science in chemistry or physics or biology to what tentative general conclusions, if any, their researches were leading them. He was a great appreciator and conciliator, and many workers in more specialized fields must feel grateful to him for his breadth of outlook and his unshaken faith in "Man's Unconquerable Mind".

John W. Harvey.

We regret to announce the following deaths:

Major P. H. G. Powell-Cotton, founder of the Powell-Cotton Museum of big game at Birchington, on June 26, aged seventy-three.

Sir Raymond Unwin, an authority on town planning, aged seventy-six.

NEWS AND VIEWS

Wildlife in the Channel Islands

THE German occupation of the Channel Islands interrupts a good number of years of continuous, sound biological field work conducted by the Jersey Branch of the British Empire Naturalists' Association amongst a fauna and flora unique in the British Isles for representing the northern limits of many Mediterranean species. Its air fauna has been shown to be rich in nesting species like peregrine, puffin, raven, guillemot, razorbill, oyster-catcher and various gulls, while the flora includes the first European station for the American club-rush (*Scirpus americanus*), which was probably introduced to St. Ouen's pond by wildfowl, the only British station for the Jersey bugloss, and also the yellow broomrape. There are also such interesting plants as sea-scabious, spotted rock rose, the beautiful hyssop-leaved loosestrife, clustered trefoil, four-leaved alseed, evergreen alkanet, spreading star-thistle, five-spotted catchfly, French pink and proliferous pink growing about the quarries, the cliffs, or the shore.

The Rev. P. Burdos and Mr. H. J. Baal have for some years made a study of the bird life of the islands, and Mr. E. R. Casimir has recorded much of the flora. In winter the islands are so mild that at Christmas it is the normal thing to find some forty species of plants in flower. A great deal of low-tide research has been carried out at L'Etacq under the supervision of Mr. Baal and others, and the marine specimens exhibited at the States of Jersey Library; butterflies on the Queenevais were also watched and recorded, especially in relation to the migrations from France to Britain. Special efforts were made to conserve the wild life in the pretty Belle Hougue valley. Recorders have long debated whether records from the Channel Islands (and from the Scilly Isles) should not be credited to the British list, but to the French lists. The geology is mostly French, although where the granite predominates the scenery resembles Devon and Cornwall.

Purchase Tax on Books

MR. KENNETH LINDSAY asked the Chancellor of the Exchequer in the House of Commons on July 2 whether he would exclude the book trade from the Purchase Tax, in view of the dependence of book exports on the volume of home trade and the vital importance of the book industry to the moral of English-speaking peoples, but Sir Kingsley Wood said that he had given careful and sympathetic consideration of the matter, and regretted that he could not exempt the publishing trade from making this contribution to the revenue needed for the prosecution of the war. It is legitimate comment on this reply to point out that while the tax is collected from the publishing trade, the cost of the tax must fall on the public. As we have already pointed out (NATURE, May 11, p. 719), it is against the public interest both from the financial and the intellectual point of view to place a check on the sale of literature, a substantial proportion of which represents export business. The position is totally different from that in many other industries, where export trade does not depend on sales in Great Britain, and where it is desired for various reasons to reduce consumption at home. It is to be hoped that the Government may yet find a way of relieving the industry of the proposed burden.

Shortage of Ergot

AN open request has been made to medical practitioners by the War-time Requirements Committee appointed by the Medical Research Council to observe strict economy in prescribing ergot. This is one of a remarkably small number of important drugs which have become scarce since the War began. The primary reason for the scarcity is not the present War so much as the Spanish Civil War, for Spain has not recovered her trade in this valuable item of *materia medica*, which was neglected during the period of domestic strife. Other countries which supplied substantial quantities of ergot were the U.S.S.R., Poland and particularly Portugal. Supplies of Russian material available to other countries have been steadily diminishing for the past two years, because the bulk of the output is reserved for use in Russia itself. The cessation of Polish supplies was, of course, a direct consequence of the War. In the last two years, the crops of Portuguese ergot have been below normal; indeed it is said that the last crop was a failure. Thus the world outside Germany and certain mid-European countries where sufficient quantities of the drug are produced for domestic requirements has had to depend mainly upon the diminished output of Portugal. Very large quantities of ergot, which is a fungus parasitic on the rye plant, are prescribed in general midwifery practice and in maternity hospitals, but it appears to be the view of the Medical Research Council that the prescription of ergot could be greatly reduced without prejudice to patients.

Royal Aeronautical Society: New President

MR. GRIFFITH BREWER, who is an honorary fellow of the Royal Aeronautical Society, has been elected president of the Society for the year 1940–41. Mr. Griffith Brewer was born in London in 1867 and commenced ballooning so long ago as 1891. When Wilbur Wright went to France in 1908, Mr. Brewer was his first English passenger. From then on he devoted his attention to aeroplanes and in 1914 learnt to fly at the Wright Field at Dayton, Ohio. During the War of 1914–18 he was honorary adviser to the Airship and Kite Balloon Services at Roehampton from 1915 onwards, and made experiments with ripping kite balloons in the air after breaking of the cable for the R.N.A.S. during 1917–18. In 1912 he founded the Wilbur Wright Memorial Lecture. More recently he has delivered addresses at Dearborn (1938) and at Massachusetts Institute of Technology (1938) on the Wright Brothers' scientific research. It was largely due to Mr. Brewer's efforts that Mr. Orville Wright has lent his original aeroplane, on which the first power flights were made at Kitty Hawk, North Carolina, to the Science Museum, South Kensington, where it has been for the past twelve years.

Philip Syng Physick (1768-1837)

IN an address recently delivered before the Royal Society of Medicine (*Proc. Roy. Soc. Med.*, 33, 145; 1940) Dr. George Edwards gives an interesting account of Philip Syng Physick, "the father of American surgery". He was born on July 7, 1768, at Philadelphia, where he graduated in the Faculty of Arts at the age of seventeen. In 1788 his father, who was receiver-general of the Colony of Philadelphia, took him to London, where he became a student at St. George's Hospital and served first as a dresser and then as house surgeon to John Hunter. In 1790 he received the diploma of the Royal College of Surgeons. In the following year he went to Edinburgh, where he obtained his doctorate with a thesis on apoplexy, which he dedicated to John Hunter. In 1792 he returned to Philadelphia, and two years later was appointed to the staff of the Pennsylvania Hospital and that of the Philadelphia Dispensary. He rapidly gained an extensive practice owing to his surgical skill, particularly in two operations, namely, enucleation of the lens, and removal of stones from the bladder. He devised several new operative methods and surgical instruments, including improved treatment of chronic ulcers, fractures and dislocations, the invention of a tonsillotome and of a forceps for controlling hæmorrhage, and various modifications of catheters.

In 1800 Physick was appointed professor of surgery at Philadelphia, and held this post until 1819, when he succeeded his nephew, John Syng Dorsey, in the chair of anatomy. He retired in 1831 at the age of sixty-three, and was unanimously elected emeritus professor of surgery and anatomy "as a tribute to his merit in elevating the character of the school and in promoting the advance of medical science". He received many honours at home and abroad. From 1824 until his death thirteen years later he was president of the Philadelphia Medical Society; in 1825 he was the first American to be elected a member of the French Royal Academy of Medicine, and in 1836 he became an honorary fellow of the Royal Medical and Chirurgical Society of London, the predecessor of the Royal Society of Medicine. He left no writings of importance, but his methods and teaching are embodied in Dorsey's "Elements of Surgery" (1813), which went through three editions, and Gibson's "Institutes of Surgery" (1824). He died on December 15, 1837.

Hagiological Healing

THE April issue of the *Bulletin of the History of Medicine* contains a richly documented article by C. Grant Loomis of Harvard University summarizing some of the aspects of miraculous healing which will be of interest to the anthropologist and folklorist as well as to the medical historian. While most of the miracles on record appear to have been accomplished solely by prayer and sincere belief in the efficacy and intercession of holy men, additional factors in a number of cases have been superadded to the simple act of faith. In some conditions, for example, such as deafness, paralysis, headache, poisoning, blindness and severed members, the efficacy of saliva has been reported (see NATURE, April 13, 1940, p. 585). The external or internal use of water in which the saint has washed himself has been employed for numerous complaints, especially blindness, fever and insanity. Other fluids such as blood from a holy corpse, sacred oil from various sources, milk from the mothers of saints and wine from the chalice or hand of a saint have also been credited with curative properties. In many instances, sacred dust, earth or mud from the houses or burial places of saints have served as the chief element in cures, while grass and flowers from their tombs have sometimes proved beneficial. Relics of all kinds have been used for various ills not only in individuals but also in the control of epidemics. All the major saints and some of the minor ones have been credited with miraculous healing power, but it was exceptional for them to have employed popular remedies.

Jewish-Christian Intermarriages in Budapest

IT has become a commonplace of sociological and economic argument that the rapid increase in facilities of transport and inter-communication between peoples geographically remote from one another has made the world 'a small place'. Evidently it has a profound biological effect upon humankind in the aggregate, diminishing steadily by interbreeding the innate biological differences that formerly existed between races and other differentiated groups of human beings. Prof. Raymond Pearl, when discussing a few years ago the future of war as a phenomenon and a social agent, stressed this tendency to uniformity in human beings as well as its effect in the slow and steady weakening of the religious and social taboos which inhibit mixed marriages. While there is general agreement that interbreeding is taking place at an accelerated pace at the present time, there is very little in the way of precise statistical observation by which this conclusion can be proved and quantified.

Valuable material pertinent to the issue has been drawn by Prof. Pearl from successive volumes of [illegible] municipal archives of Budapest, covering the period 1897–1935. From the marriages recorded in this period, of which Prof. Pearl has plotted the figures to show the trend of Christian, Jewish, and mixed marriages (*Bull. Hist. Med.*, 8, 3; 1940), it would appear that the proportion of Jewish and Christian marriages to all marriages of either Christian or Jews increased generally throughout the period and to a marked degree, being 2·6 per cent greater to all Christian marriages in 1935 than in 1897, while it was 3·05 per cent greater to all Jewish marriages in the same year. Since 1925, however, the proportion of mixed Jewish and Christian marriages to all Jewish marriages has slightly increased, whereas the proportion to all Christian marriages has declined slightly. This is attributable to a decline in the Jewish population and an increase in the Christian after 1919. There is a further tendency to be noted in the fact that a greater number of Christian brides marry Jewish men than of Jewish brides who marry Christian men. Here again there is a marked increase in the differential between the two types in the post-War years.

New World Origins

For long the amazing efflorescence of indigenous culture among the Mayas and Aztec of Central America was the only aspect of American archæology to attract the serious interests of European students. Even the intensely absorbing question of the origin, character and chronology of such alleged early skeletal remains, germane as it was to the inquiries of human palæontology and ethnic origins in the Old World, received less attention than it deserved. Extravagant claims for the antiquity of man on the American continent, readily demolished in most instances, were no doubt responsible for something more than a certain reserve in the approach to the general question. All this has to a great degree been changed, and the discovery of the Folsom point in New Mexico and other regions of the south-western United States in clear association with an extinct fauna has now placed the discussion of the antiquity of man in America and the early cultural history of the continent on a basis which enables British archæologists to enter upon the discussion of a problem conditioned by data of which they have a ready understanding and with which it may be said they have at present a closer acquaintance than their American colleagues. This is implicitly admitted by Prof. E. B. Renaud, one of the pioneers in the study of Folsom man, in his most recent published work.

The literature of Folsom man is already large ; but to those who have not been able to follow it closely, we may commend an excellent critical analysis which is part of a discussion of the whole question of New World origins appearing in *Antiquity* of June, by Dr. J. Grahame D. Clark, whose experience of analogous European stone age cultures carries great weight. His typological argument on the much debated question of the relation of the Folsom point and the more generalized Yuma point therefore deserve careful attention, although the recently discovered northward extension of the Folsom point so far as Canada may be found to have greater significance than as yet has been attached to it.

"Elephants and Ethnologists"

An echo of the famous "Elephants and Ethnologists" controversy appears in a contribution by Mr. W. Balfour Gourlay in *Man* of June 1940. This controversy, it will be remembered, turned on the alleged occurrence of representations of the elephant in the Mayan sculptures of Central America, which were held to demonstrate the Asiatic derivation of Central American culture, while others held, as it has been put, that the elephants had trampled finally on the theories of the Diffusionist School of Elliot Smith, Perry and their followers. Mr. Gourlay refers in the first place to a discovery brought to his notice at Guadalajara, Jalisco, in Mexico. Here it was stated human and elephant bones had been found in association. He did not see the find *in situ*, but his subsequent inquiries leave no doubt that the position of the human bones was due to burial.

A more intriguing evidence was observed by Mr. Gourlay in 1921. It left him in little doubt that man had lived in Central America in contemporary association with some elephant-like creature. This was a primitive and almost life-sized representation of the head of a strange animal carved from a block of black lava which then stood on a pedestal outside the museum at San Salvador. The statue, of which two photographs are shown, was about two feet high. The animal bore a trunk, too long for that of a tapir, too short for an elephant. If it was intended to represent an elephant, the artist evidently had never seen one, and did not understand its anatomy, as the eyes were placed in the middle of the ear-lobes. Sir Grafton Elliot Smith, to whom the photographs were shown, was convinced that an elephant was intended, much copying being responsible for the departure from realism ; but the author is not convinced and regards it as a problem demanding solution.

R 276

Attracting Birds

In earlier less sophisticated days the desirability of attracting birds was accepted without question. Now doubts have arisen, partly because it is recognized that some birds may do some harm to man's possessions, and partly because the congregating of birds at a common feeding ground may lead to the spread of diseases among the birds themselves. These dangers are recognized and provided for in a new pamphlet, the first of a series of Conservation Bulletins, issued by the Bureau of Biological Survey of the U.S. Department of the Interior. In it W. L. McAtee summarizes clearly and with line illustrations suitable methods of encouraging nesting, and discusses the proper foods to be supplied to a number of the commoner birds of the States. His hints apply equally well to many British birds, and particularly useful will be found a short section dealing with common cultivated annual plants which may be sown for the encouragement of seed-eaters such as siskins, gold-finches and other finches. For fruit-eating birds there is a short list of shrubs and trees the fruits of which persist into the winter, when the birds have most need of them. It is a useful list for anyone wishing to create a shrubbery likely to be appreciated by winter bird visitors.

Significance of Television

An instructive address on television given at Buenos Aires last year by Mr. W. E. Tremain, chairman of the Argentine Centre of the Institution of Electrical Engineers, is published in the May issue of the *Journal of the Institution of Electrical Engineers*.

Mr. Tremain begins by saying that the more we study recent developments in television, the more we are forced to realize that high-definition television is one of the outstanding scientific and engineering achievements of our time. In August 1936, the Alexandra Palace transmitter in north London was in full operation, giving the first public television service in the world. On May 12, 1937, the Coronation procession was televized with much success. It was the first outside television exhibition of importance. In conclusion, Mr. Tremain points out that television is destined to play in the future a leading part both as a means of communication and as a means of instruction. When planning for the future, it is important to bear this in mind. In England, as a result of pressure both from the cinema and radio industries, the experimental work being conducted for the purpose of extending the television service in the provinces was expedited. If a definite decision be taken with this end in view, we can look forward hopefully to it giving much direct employment in happier times.

Standardizing Electric Distribution Cables

MR. S. W. MELSOM, of the staff of the Cable Makers' Association, has contributed a paper on the standardization of cables and equipment, with the object of reducing distribution costs, to the *Electrical Review* of June 7. Discussions have been going on for several years in order to frame an acceptable set of rules. The outbreak of war prevented the embodiment in the revised British Standard Specification for mains cables of the discussions during the last two or three years. The selection of standard sizes for cables to be used in a low-voltage network is a matter almost entirely for the supply engineers. It is difficult to forecast accurately the load which a distributor will have to carry, and since the data on which estimation has to be based are somewhat nebulous, there are strong reasons for the adoption of a few—possibly not more than two—standard sizes for a given system of low-voltage four-core cables.

Since the size of the undertaking and the load-density in the cable must vary between districts, it has been suggested that three sizes of four-core cable are required, namely, 0·1, 0·2 and 0·3 sq. in., the smaller sizes being sufficient for the smaller systems and the larger for larger systems. Some suggest also that it would be more economical to use shaped and not circular conductors. The initial difficulties experienced in the construction of this type of cable have been overcome by the use of special apparatus. It is believed that the shaped conductor is quite as satisfactory as a circular conductor and is better technically. Difficulties have been experienced as to the best colours to use to identify the cores. The proposals that have been put forward envisage leaving the colours to the switchboard manufacturers and using numbers for the identification of cable cores. The questions of factor of safety and cost, now nearing solution, have involved a very large amount of work on the part of designers, research laboratories and testing authorities and great improvements are in immediate prospect.

An Automatic Distress Signal

THE Ministry of Shipping has given its approval to the 'Raft-o-Lite' safety flashing light of the International Marine Radio Co., Ltd., 63 Aldwych, W.C.2. It comprises a battery and light in a water-tight case, provided with a float so that it will assume a vertical position when floating in the sea. A flasher is incorporated with it and this is designed to emit automatically the international distress signal 'S.O.S.'. When stored in an inverted or horizontal position the light is not in use, but when thrown into the water it assumes a vertical position and the flashing light is automatically switched on, continuing for forty-eight hours at least. The manufacturers point out that these lights are particularly suitable for oil-burning ships and tankers, where oil on the water may render dangerous the use of open flares.

Breeding of Herbage Plants in Scandinavia and Finland

JOINT PUBLICATION No. 3, "The Breeding of Herbage Plants in Scandinavia and Finland" of the Imperial Agricultural Bureaux of Aberystwyth and Cambridge contains considerable information on the breeding of clovers and pasture grasses in Norway, Sweden, Denmark and Finland. The contributors are S. Nilsson-Leissner, F. Nilsson, E. Åkerberg, R. Torssell, H. N. Frandsen, H. Wexelsen, and O. Pokjakalliv. A significant feature of the work in these countries is that the breeding work on a given crop has led to the country becoming independent of foreign seed for that crop. It was found, for example, that selection of late strains of red clover from local strains improved the yield by 10 per cent, and such selections are now so popular in Denmark that it is unnecessary to import seed. Similar results are reported from Norway and Sweden, where resistance to *Sclerotinia trifoliorum* and Tylenchus, 'persistance' and winter hardiness are of particular importance.

Both in red clover and timothy grass, inbreeding has been found to lead to drop in yield, vigour and fertility, while the 'hybrid corn method' of crossing inbred lines to produce heterosis is scarcely practicable. It is found preferable to adopt plant selection and cross breeding to give natural selection full scope. Frost hardiness is selected for by removing the snow from timothy plants. Alsike and white clover together with various species of Lolium, Festuca, Poa, Agrostis, Dactylis, Bromus and other genera are being bred for commercial work. The more important varieties which have been raised and a list of the many plant-breeding stations in Scandinavia which are given in this useful publication indicate the extent of the work in progress.

Map of Antarctica

THE Antarctic regions have been of official interest to Australia since 1933, when the Commonwealth Government announced its claim to a large sector of the continent south of the Indian Ocean between the Ross Dependency of New Zealand and Enderby Land. The Australian Antarctic Territory embraces about one quarter of the Antarctic regions. The

Commonwealth Government has now published a two-sheet map of Antarctica by Mr. E. P. Bayliss (Department of External Affairs, Canberra. With handbook. 7*s.* 6*d.*). The map is on an azimuthal equidistant projection and has a latitudinal scale of 1 : 7,500,000. Known land, revised to the most recent discoveries, is shown in brown with valley glaciers in blue. Prominent peaks and heights in metres are shown. The ocean is blue, with soundings and bathymetrical contours. The names of the chief discoverers of lands are shown, and the territorial claims are indicated on the main map and on a smaller scale inset which shows relation with the southern continents. The recently claimed Norwegian sector is not marked as such. The coastal areas of the Australian Antarctic Territory are shown on another inset on a scale of 1 : 5,250,000. On many coasts the tendency to replace the term 'land' by 'coast' has been followed, but where no general name exists the multiplicity of 'lands' remains. The map is an excellent piece of work, with much detail, and is clearly printed. It should prove a standard map for some time. The accompanying handbook gives an account by Mr. J. S. Cumpston of recent exploratory works and cites most, but not all, of the authorities and explorers' records. It contains also an index to the map.

Pasteur Institute of India, Kasauli

It is announced in the thirty-eighth annual report of this Institute, recently issued, that the anti-rabic treatment which has been carried on here for forty years has been transferred to the Central Research Institute, Kasauli. The Kasauli Pasteur Institute was formally opened for the treatment of dog-bite and similar cases in August 1900 under Major David Semple, R.A.M.C. It was the first Pasteur Institute to be established in the British Empire; in the first year 321 persons were treated, and the numbers increased year by year until in 1938 more than 22,000 persons received treatment. During its last year, 1938, 20,377 Asiatics and 1,817 Europeans received anti-rabic treatment at Kasauli and its associated centres, with 73 deaths, a mortality of 0·33 per cent, the lowest figure during its long history.

Demography of Eire

According to the recently published returns of the March quarter, the marriages registered in Eire during this period numbered 3,509, which was equivalent to an annual rate of 4·7 per thousand of the estimated population, this rate being equal to that for the corresponding quarter of 1939. The number of births amounted to 14,110, of which 7,228 were of males and 6,882 of females. This represents a rate of 19·1 per thousand of the population, being 0·3 below the rate for the first quarter of 1939. The total included 460 illegitimate births, equivalent to 3·3 per cent of the total births recorded. The number of deaths registered during the quarter was 13,376, of which 6,887 were of males and 6,489 of females. The equivalent annual rate was 18·1 per thousand of the estimated population, being 0·1 below the rate for the first quarter of the preceding year.

Juvenile Literature

"500 Books for Children", by Nora E. Beust (Washington, D.C., 15 cents), is a pamphlet with a sound idea behind it. Capable selections from the present overgrown jungle of books are a great help, if not a necessity. The list is well arranged in three sections of advancing age and indexed with cross-references. With a host of new books, old favourites still keep their places, such as Kingsley's "Heroes", "Treasure Island", and Kipling's "Mowgli" and "Just So" stories. We looked for some time for the two immortal "Alices" and at last found them under C. L. Dodgson, who never would admit that he wrote them. Animals, flowers and Nature in general are well represented. Children can even get an idea of what happens inside the atom. The illustrations show two designs which have won special medals.

Announcements

General de Gaulle, leader of the French Volunteer Legion, has appointed M. André Labarthe director-general of all French services connected with armaments and scientific research in Great Britain. M. Labarthe, who is thirty-eight years of age, has appealed to French engineers, men of science, and industrial workers to join the already large number of their colleagues who have enlisted as civilian workers in the Legion.

The Minister of Labour and National Service has appointed Sir William Beveridge, master of University College, Oxford, and formerly director of the London School of Economics and Political Science, as commissioner to survey the available resources of man-power of all kinds and to report thereon with suggestions on the means by which these resources can be utilized fully for national purposes. The office of the survey will be at the Ministry of Labour and National Service, Montagu House, S.W.1, and Mr. A. Reeder, deputy director of statistics in the Ministry, will act as secretary to the survey.

The Summer School in Social Biology arranged by the Educational Advisory Board of the British Social Hygiene Council, which was to have taken place at Westminster College, Cambridge, during August 1–8, has been postponed until the advent of more favourable circumstances.

Dr. Charles Slater, consulting bacteriologist to St. George's Hospital, London, who died on March 15, bequeathed £10,000 to St. George's Hospital for teaching bacteriology or research work in that science, £5,000 to the University of Manchester for the equipment and maintenance of the laboratories, and £4,000 to the University of Cambridge for teaching or research work in medical science.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Fission Products of Uranium produced by Fast Neutrons

IN continuation of our experiments on the fission of uranium by fast neutrons, we have been studying decay periods of various isotopes. In this communication we give the results on silver and cadmium isotopes.

The uranium oxide, U_3O_8, carefully purified and freed from its disintegration products just before the experiments, was exposed to fast neutrons produced by bombarding lithium with 3 Mev. deuterons of several microamperes from our cyclotron, as described in our earlier note[1]. The exposure ranged from a few hours to some fifty hours, according to the object of the experiments. From the irradiated sample, silver was separated as iodide or chloride, cadmium as sulphide. Each fraction, carefully freed from the known fission products of uranium such as barium, lanthanum, antimony, tellurium, iodine, molybdenum, etc., was examined for its activity.

The decay curves of the silver fraction, which were obtained from samples exposed for some fifty hours, showed two periods, 7·5 days and 3 hours. The former activity is probably identified with ^{111}Ag [2,3] and the latter with ^{112}Ag [3].

The decay curves of the cadmium fraction, which was obtained from long exposures, showed apparently three periods, fifty minutes, several hours and 2·5 days. The first activity is possibly an isotope reported by Dodé and Pontecorvo[4]. The second one was proved to be ^{117}Cd by the identification of indium activity produced through its series transformation in the following way. Cadmium sulphide from a sample irradiated for 3 hours was dissolved in hydrochloric acid three hours after the initial separation of cadmium. The solution, after an addition of indium nitrate, was treated with an excess of ammonia. The precipitated indium hydroxide was filtered off and examined for the activity. Its half-period was found to be 2·1 hours, which is due to the known isotope of indium ^{117}In [5]. We thus conclude that the activity of the cadmium fraction is due to ^{117}Cd, the half-life of which turns out according to our measurements to be about 5·5 hours.

Similar procedure was taken with the 2·5-day activity. The cadmium sulphide from an irradiated sample of long exposure was left for about twenty hours before dissolution in hydrochloric acid, until the cadmium isotope ^{117}Cd and its daughter product died away. The indium fraction obtained in the same way as above was examined for activity, and a half-life of 4·5 hours was obtained, which we identify with the known radioactive isomer of the stable indium isotope $^{115}In^*$ [5]. As a consequence, we conclude the 2·5-day activity to be due to a cadmium isotope ^{115}Cd.

It should be mentioned that Be + D neutrons from our cyclotron, and also neutrons slowed down by paraffin, do not appreciably produce silver and cadmium activities as above mentioned. The details of the experiments will shortly be given elsewhere.

The above investigations were carried out as a part of the programme of the Atomic Nucleus Sub-Committee of the Japan Society for the Promotion of Scientific Research. We acknowledge the assistance given by our laboratory colleagues in connexion with the irradiation of samples and by Messrs. N. Saito and N. Matuura regarding the chemical separations.

Mass-Radius Relation for a White Dwarf Star

THE peculiar difficulty pointed out by Eddington regarding the ultimate fate of a white dwarf star led Fowler[1] to make the first application of Fermi-Dirac statistics to astrophysics in a fundamental paper which initiated a long series of investigations, particularly by Milne[2], in recent years. The starting point is the expression

$$a(\varepsilon)dt = \frac{gV(2m)^{3/2}}{4\pi^2\,\hbar^2}\ \varepsilon^{1/2}\,dt, \tag{1}$$

which represents (neglecting the effect of relativistic mechanics) the number of wave functions corresponding to eigen-values lying in the energy-range ε to $\varepsilon + dt$ for a *free* electron confined in a field-free region of volume V; this is assumed to hold for the stellar interiors though gravitational and electrical fields are present. For degenerate matter equation (1) leads to the well-known expression for the pressure

$$p = \frac{32\pi^3}{15}\,\frac{\hbar^2}{m}\left(\frac{3\rho}{4\pi g\mu m_H}\right)^{5/3}; \tag{2}$$

which reduces the equation for mechanical equilibrium for a star to Emden's equation of index 3/2 giving the relation ("Emden-solution")

$$R = \frac{\alpha_0 L_0}{\mu^{5/3}}\left(\frac{\odot}{M}\right)^{1/3} \tag{3}$$

between the radius R and the mass M of a white dwarf. L_0 is a length characteristic of the white dwarf theory

$$L_0 = \frac{\hbar^2}{m\, m_H^{5/3}\, G\, \odot^{1/3}} \doteqdot 6{\cdot}18 \times 10^8 \text{ cm.}, \qquad (4)$$

and

$$\alpha_0 = \left(\frac{9\pi^2\, \omega^\circ_{3/2}}{128}\right)^{1/3} \doteqdot 4{\cdot}51, \qquad (5)$$

where $\odot$ is the solar mass, m the mass of the electron, m_H the mass of the proton, G the gravitational constant, and $\omega^\circ_{3/2} = 132{\cdot}4$ is a number defining the Emden-solution of index 3/2. μ is the mean molecular weight per free electron, $\mu = 1$ for ionized hydrogen and $\mu = A/Z \doteqdot 2$ for any other completely ionized element of atomic weight A and atomic number Z. (The material in the interior of a white dwarf star is completely ionized due to pressure ionization.)

In the case of Sirius B—the most accurately known amongst the white dwarfs—the calculated radius for $\mu = 2$ (hypothesis of hydrogen scarcity) is smaller than the observed value by a factor somewhat larger than 2, but is in accord with observation if the stellar material is assumed to contain about 70 per cent of hydrogen by weight (hypothesis of hydrogen abundance).

However, the hypothesis of hydrogen abundance, as recently emphasized by Eddington[3], Wildhack[4], and Marshak and Bethe[5], is in violent disagreement with the theory of stellar energy generation. It predicts for the white dwarf a luminosity of an order far higher than the observed value, and so it must be discarded. With the elimination of the hypothesis of hydrogen abundance, relation (3) no longer remains in accord with observation.

The present note is concerned, *first* to direct explicit attention to the importance of the electric field in the theory of a white dwarf star, and *secondly* to give a derivation of the mass-radius relation (without recourse to equation (1)) which indicates a possibility of removing the discrepancy noted above between the observed and the calculated radii. We shall for simplicity consider a uniform-density model. As Rosseland[6] showed long ago, an electrical field is set up in a star which prevents any appreciable separation between the free electrons and the atomic nuclei, and for a model of uniform density we must have

$$A m_H u + Z e V = 0, \text{ or } ev = -\mu m_H u, \qquad (6)$$

where u is the gravitational and v the electrostatic potential (both measured from the centre : $u = v = 0$ at $r = 0$). If ξ denotes the Gibbs' free energy per electron, then, from a well-known theorem in thermodynamics, we have

$$\xi_0 - \xi_1 = m u_1 - e v_1 = \mu m_H u_1, \qquad (7)$$

where the suffixes zero and one represent the values at the centre ($r = 0$) and the surface ($r = R$) respectively. ($m u_1 - e v_1$) is the work done in carrying an electron from the centre to the boundary. For degenerate electron gas, if n represents the free electron concentration,

$$\xi = \frac{h^2}{2m}\left(\frac{3n}{4\pi g}\right)^{2/3}, \qquad (8)$$

a result which is ultimately based on (1). Substituting $\xi_1 = 0$ and $u_1 = GM/2R$, we have from (7) and (8)

$$R = \frac{\alpha_1 L_0}{\mu^{5/3}}\left(\frac{\odot}{M}\right)^{1/3}, \qquad (9)$$

$$\alpha_1 = \left(\frac{9\pi}{4}\right)^{2/3} \doteqdot 3{\cdot}68\,; \qquad (10)$$

which is practically identical with (3), and is exactly the expression that is obtained by an application of the *virial* theorem[7]. If the electrostatic field be ignored, we obtain instead of (9) a relation of entirely different order of magnitude, namely,

$$R = \frac{m_H}{m}\,\frac{\alpha_1 L_0}{\mu^{5/3}}\left(\frac{\odot}{M}\right)^{1/3}. \qquad (11)$$

The above discussion brings out explicitly the importance of the electric field in white dwarf theory. We shall now consider the derivation of the mass-radius relation from a different point of view, which appears to be more fundamental.

The Schrödinger equation for an electron inside a white dwarf is

$$\nabla^2\Psi + \frac{2m}{\hbar^2}(E - mu + ev)\,\Psi = 0, \qquad (12)$$

which on using (6), and substituting for a sphere of uniform density

$$u = \frac{GM}{2R^3}\, r^2, \qquad (13)$$

reduces to

$$\nabla^2\Psi + \frac{2m}{\hbar^2}(E - \tfrac{1}{2}\alpha r^2)\,\Psi = 0, \qquad (14)$$

where

$$\alpha = \mu m_H \frac{GM}{R^3}, \qquad (15)$$

This is the wave equation for a harmonic oscillator and gives for E the eigen-values

$$E_l = \hbar\left(\frac{\alpha}{m}\right)^{1/2}(l + \tfrac{1}{2}), \qquad (16)$$

where l is any positive integer. The number of independent wave functions associated with the eigen-value E_l is $gl(l+1)/2$, where g is the weight factor ($g = 2$). In the *degenerate* case the levels from $l = 0$ to $l = l_0$ will be completely filled up, that is, $\sum_0^{l_0} l(l+1)$ would be equal to the total number of electrons ; hence

$$l_0 = \left(\frac{3M}{\mu m_H}\right)^{1/3}. \qquad (17)$$

The amplitude of the oscillator corresponding to the maximum energy E_{l_0} is to be identified with the radius R, and thus we have $E_{l_0} = \frac{1}{2}\alpha R^2$, which gives

$$R' = \frac{\alpha_2 L_0}{\mu^{5/3}}\left(\frac{\odot}{M}\right)^{1/3}, \qquad (18)$$

$$\alpha_2 = (24)^{2/3} \doteqdot 8{\cdot}32. \qquad (19)$$

This is the same relation as (3), but the numerical factor is 1·84 times larger. For Sirius B, (18) gives $R = 1{\cdot}6 \times 10^9$ cm., whereas the observed value is 2×10^9 cm.

The theory here given needs to be refined in many ways ; thus the effect of electron collisions will be to broaden the energy levels, and it might be taken account of in the same way as in the theory of diamagnetism, but nevertheless it is interesting that the mass-radius relation has been obtained in this way.

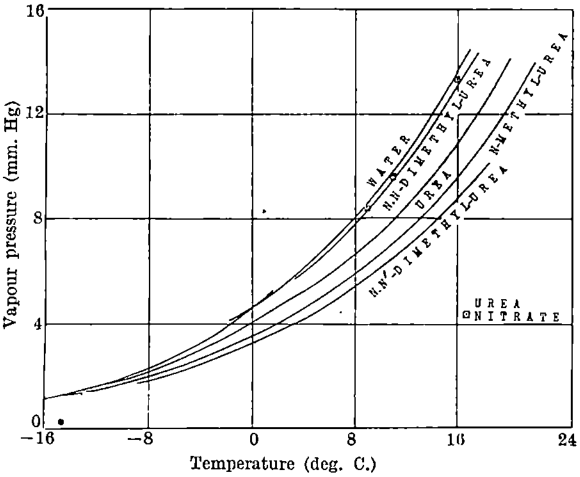
Deliquescence in Urea and Methyl-ureas

A COMMUNICATION in NATURE from E. A. Werner[1] directed attention to the deliquescence of urea and to the paucity of data concerning the vapour pressures of saturated solutions of urea and its derivatives, apart from the few observations of Adam and Metz[2], and Edgar and Swan[3]. The accompanying figure gives vapour pressure curves for saturated solutions of urea, urea nitrate, N-methyl-urea, N.N- and N.N′-dimethyl-urea determined by the method described by Rowley[4], and records the quaternary point for the system, urea, ice, saturated solution, vapour (−11·3° C.) for the first time.



The vapour pressure curves confirm the observations of Werner upon the absorption of water by urea, etc., the vapour pressure of a saturated solution of urea being at all temperatures below 20° C. less than 14 mm. of mercury; consequently urea will show deliquescence except under conditions of unusually low humidity. The actual humidity required to cause deliquescence in these compounds, expressed as a percentage of the maximum vapour pressure of water at 18° C., is:

Urea nitrate	>95
N.N-Dimethyl-urea	94·3
Urea	80·1
N-Methyl-urea	70·0
N.N′-Dimethyl-urea	63·5

This shows N.N′-dimethyl-urea to be of the order of deliquescence of ammonium nitrate, urea and N-methyl-urea of sodium nitrate, and N.N-dimethyl-urea and urea nitrate of potassium nitrate.

The marked difference in the deliquescence of the methyl ureas is of interest on account of the various structures suggested for these compounds[5].

Examination of ‘Egyptian Blue’ by X-Ray Powder Photography

X-RAY powder photography has been carried out upon various examples of the brilliant azure pigment known as ‘Egyptian Blue’. It has been found as early as the Fourth Dynasty (2900–2250 B.C.) and its use became very widespread throughout the Roman Empire. By this method crude frits from Tel-el-Yehoudi (Egypt), Silchester (Berkshire) and Woodeaton (Oxfordshire) have been shown to be of the same crystal form as a block already prepared for trading from Tel-el-Yehoudi, another in course of preparation from Armant (Egypt), and pale blue finely powdered pigment on pottery from Tel-el-Amarna (Egypt), and on wall plaster frescoes from Woodeaton. A potsherd from Woodeaton contained the same finely powdered pigment and was obviously used as a palette. All these examples were shown to contain essentially copper, calcium, and silica, with varying small amounts of sodium. Laurie and others[1] had previously shown that examples of a similar blue from Egypt, Rome, Knossos (Crete), Syria, and Wroxeter (Shropshire) consisted essentially of a definite compound—$CuO.CaO.4SiO_2$, which assumes this brilliant azure only if formed between 800° C. and 900° C.; outside these limits the frit passes to a green glassy mass.

The crude frits were found in the form of agglomerates of small balls about $\frac{1}{2}$ in. in diameter, and this agrees remarkably well with Vitruvius's description (*c.* 24 B.C.) of the making of the pigment:

“Caeruleum was first made at Alexandria, then by Vestorius at Puteoli. . . . Sand and Natron (native Soda) are powdered together as fine as flour and Copper is grated by coarse files over the mixture. This is made into balls by rolling in the hands. The dried balls are then put into an earthen jar, which is put into a furnace. When the Copper and Sand have coalesced in the intense heat and the separate things have disappeared, the colour Caeruleum is made.” The biconical form of the balls, resulting from rolling in the hands, is especially noticeable in the examples studied.

The application of X-ray powder photography to the study of this pigment provides a simple means of establishing its identity, even in the finely powdered form as it appears in paintings; thus it was possible to identify copper aluminate, $CuAl_2O_4$, as being responsible for the blue colour on one pot from Tel-el-Amarna. It is hoped to extend the use of this method in the technological examination of antiquities.

Attainment of the Upright Posture of Man

IN his recent paper entitled “Fifty Years Ago”[1], Sir Arthur Keith tells how, when in Siam in 1890, he became impressed by the similarity in muscular and visceral adaptations shown by the hand-swinging gibbon and bipedal orthograde man. The gibbon suspends its body in an upright posture by hanging from its hands; man maintains his upright posture by standing on his feet. It was, therefore, an easy step to assume that the brachiating gibbon had paved the way to human uprightness. The story of this assumed transition is most graphically told in Sir Arthur Keith's little book "The Human Body", and it has become the creed of what W. K. Gregory of New York terms "the orthodox school". This brachiating hypothesis of the origin of man's upright attitude has been accepted by practically all English-speaking anthropologists and palæontologists. We may cite the Romanes Lecture of 1928 by Prof. D. M. S. Watson, the works of the late Sir Grafton Elliot Smith and many others in its support. This orthodox school, as represented by Gregory, claims that the brachiating habit is "a necessary introduction to the upright posture of Man", and man is defined by the same authority as "a made-over brachiator adapted to life on the ground" ("Man's Place among the Anthropoids", 1934).

This brachiating hypothesis of the origin of human uprightness I have had the temerity to contest for many years. In "Man's Place among the Mammals" (1929) I have set forth more fully the reasons that had made me reject the thesis in my first publication on the subject in 1916. In brief, I have always maintained: (1) that bodily uprightness was attained in the most primitive haplorrhine Primates long before the brachiating specialization of the anthropoid apes had been acquired; and (2) that as these primitive Primates showed the primitive condition of having the hind limb longer than the fore limb, it was, at least, unlikely that the human stock had ever become specialized as a brachiating form, with the fore limb longer than the hind limb (as is the case in all anthropoid apes) and afterwards reverted to the primitive condition of having the hind limb longer than the fore limb, as is the case in all known stages of the human phylum.

Perhaps I may be permitted to quote from Gregory, who has stated my views in his own language: "Professor Wood Jones has sought to depreciate the resemblances of the brachiating skeleton of the Gibbon to the upright bipedal skeleton of Man by claiming that the habit of brachiation has led to over-specialisation for arboreal life and has for ever prevented the anthropoids from entering upon the human path of evolution" (*op. cit.*, p. 17). This very fair statement of my views was made by Gregory in order to show how thoroughly biased and how completely erroneous they were. It is, therefore, of some interest to find that, towards the end of his latest paper, Sir Arthur Keith says: "I will add here two brief notes. (1) At that time I regarded the Gibbon as a representative of the pioneers of the orthograde stock and that Man and the great anthropoids had passed through a hylobation phase of evolution. It would take me too far afield to give the evidence which led me to abandon this opinion. Suffice it to say I now think that when the Gibbons were in their early stages of evolution (*probably in late oligocene times*) and developing along brachiating lines, two other modes of orthograde posture were also being evolved in the same stock. In one, both arms and legs were being used almost equally—the ancestral form of Gorilla and Chimpanzee; in a third—the ancestral human orthograde stock—the lower limbs were being developed as the chief organs of support and locomotion. All were arboreal in habitat". In this passage I have italicized one paragraph and will refrain from employing it as a direct negation of the views of the "orthodox school" and to Sir Arthur Keith's own published statements as to the period of divergence of the human stock from the phylum of the Catarrhini. Were I to be writing in the reminiscent strain of "Fifty Years Ago" I would record my satisfaction that Sir Arthur Keith and I (who was his student in 1897) are now in accord on this matter. If, as Sir Arthur postulates, the lower limbs of the human stock were becoming developed as organs of support and locomotion in "late oligocene times", it seems obvious that those adjustments regarding the position of the human stock in the phylum of the Primates, which I have long advocated, are no longer to be stigmatized as being unorthodox. One may indeed be permitted to wonder if those of the "orthodox school", deserted by the originator of the "brachiating hypothesis", will remain suspended by their hands or will descend to earth. In any event, their descent to earth will, like that of the existing anthropoid apes, indelibly bear witness to their apprenticeship of brachiating.

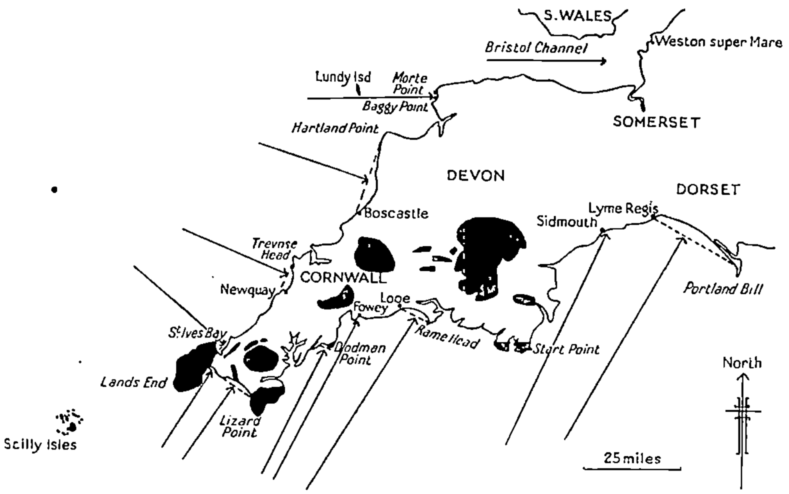
Outline of South-West England in Relation to Wave-Attack

A THEORY has recently been put forward by Mr. W. V. Lewis[1] that the general line of a shore tends to be at right angles to the direction of dominant wave-attack, and he points out that while a stretch of coast is in the process of adjustment to this attack, bays tend to become asymmetrical with the longer, smoother side facing the quarter from which the dominant waves approach. Among other examples, he cites the Chesil Beach from Chesilton to West Bay, and the coast of the Bristol Channel near Weston-super-Mare, where smooth stretches of shore face towards the open sea at right angles to the direction of dominant wave-approach.

It seems possible that this theory may be applicable to phenomena on an even larger scale, and that the major features of the coastal outline of Cornwall, Devon, west Dorset and west Somerset may be broadly interpreted on the same hypothesis. The south coast of the peninsula is divided into large bays by the headlands of the Land's End, Lizard Point, Dodman Point, Start Point and Portland Bill. In each of these bays, the western side (facing in a more or less easterly direction) is much indented into minor bays, divided by angular promontories, while the eastern side (facing south-west) is comparatively smooth, with blunted headlands. If, in each bay, a line (indicated by an arrow on the accompanying sketch-map) be drawn at right angles to the chord of the smoother eastern arc (shown by dots), it is found that its direction of approach to the coast is approximately from the south-west, and hence from the nearest part of the open Atlantic, clear of Cornwall and Brittany. The smoother eastern side of the bays therefore faces the dominant waves which approach from the nearest part of the open ocean.

In each bay, that deduced line of wave-approach from the south-west which passes the boundary-headland at a tangent is found to reach the coast at, or somewhat to the west of, the apex of the bay, where the indented western stretch turns to the smoother eastern arc. This shows how the form of the bay is directly controlled by the superior resistance to erosion of the rocks of the major headlands (marked on the map in solid black). The Land's End is a granite mass, and the Lizard, Dodman and Start Points consist of Pre-Cambrian igneous or metamorphic rocks. The irregular western stretch is that which is protected by the major headland to the west of it, while the smoother eastern arc is that on which the waves can act directly. The stretches from Lyme Regis to Sidmouth, and from Looe to Fowey, between the apex of the bay to the east and the point to the west where the headland-tangent strikes the coast, may be regarded as not yet fully aligned by the wave-attack, and these stretches are likely, even when ultimately adjusted, to remain always more curved than the coast farther to the east, on account of the waves being deflected by the proximity of the boundary-headland. The coast between Start Point and Rame Head also remains at present irregular, since the drowning of the estuaries appears to be the primary factor controlling its outline.



SKETCH-MAP OF SOUTH-WEST ENGLAND; OUTCROPS OF IGNEOUS AND METAMORPHIC ROCKS IN SOLID BLACK. ARROWS INDICATE ASSUMED DIRECTIONS OF CONTROLLING WAVE-ATTACK.

A corresponding form of bay, with a smoother eastern arc and indented western stretch, is found also on the north coast of Cornwall and Devon. Here, as on the south coast, the dominant waves offshore presumably approach from the open Atlantic to the south-west, but their impact on the north coast is therefore oblique, so that it is not these waves which produce the maximum effect on the shoreline. The smoother eastern arc of St. Ives Bay, and the chords running from Trevose Head to Newquay, from Hartland Point to Boscastle, and from Morte Point to Baggy Point, face north of west or west, and probably it is from the open Atlantic in this direction, clear of Ireland, that the largest waves can approach approximately at right angles to the coast, and thereby model the shoreline. Between Morte Point and the area already described by Mr. Lewis near Weston-super-Mare, the general lie of the coast of the Bristol Channel is east and west, parallel to the direction of wave-attack and therefore relatively little affected by it.

I wish to thank Mr. W. V. Lewis for his helpful criticism of these suggestions, which are put forward tentatively as being at present only of rough application. I am hoping later to be able to make a more detailed study of the factors controlling the outline of south-west England.

Vitamin-Free Diets for Animal Experiments

IN GREAT BRITAIN many workers on vitamins have used basal diets containing rice starch as the sole or predominant source of carbohydrate. In our laboratory that practice has been followed over many years for diets used in work on vitamin A, vitamin B_1, the rat 'filtrate factor', the 'eluate factor' (vitamin B_6) or vitamin E.

The difficulty of obtaining from our usual sources further supplies of rice starch after the outbreak of war led us to investigate the possibility of replacing it by wheat starch. We have found that this has in no way impaired the suitability of our diets used for work on vitamin A, vitamin B_1 or vitamin E.

Thus, 22 male and 10 female newly weaned Wistar albino rats, of the London strain, were fed upon our standard vitamin A-free diet, in which the change of starch had been made; all the animals reached a growth plateau in the usual time—25–31 days—and all animals receiving no supplementary vitamin A died within 40 days. Those animals that received, from the time of reaching a growth plateau, a twice-weekly dose of the International Standard Preparation of vitamin A, corresponding with daily intakes of 2 or 4 international units, responded normally. Of the 20 animals receiving no supplement, 14 developed xerophthalmia; of the 12 afterwards given vitamin A, 4 at some time showed signs of xerophthalmia, which disappeared before the experiment ended. These and other similar results are indistinguishable from those obtained with the diet containing rice starch.

Again, 65 animals receiving our vitamin E-free basal diet, in which the change of starch had been made, were positively mated to normal bucks: all underwent typical gestation-resorptions.

On the modified vitamin B_1-free basal diet, 32 males and 6 females ceased to show any increase in weight after 14–20 days. After 21 days administration of vitamin B_1 (crystalline aneurine chloride hydrochloride, 2·25 and 4·5 μgm. per day) 13 males and 1 female showed normal increases in weight. Of 6 males and 4 females receiving no supplement of vitamin B_1, 9 died between the thirty-eighth and the forty-seventh day of the experiment, most of them after a marked rapid decline in weight and with external symptoms (vertigo) of avitaminosis-B_1. (One male survived a test period of 56 days without supplementary vitamins, showing no loss or gain on his starting weight.) Here again, replacement of rice starch by wheat starch produced no demonstrable effect.

We have, however, found wheat starch unsuitable for diets used in work on the rat 'filtrate factor'. Our animals never reach a true growth plateau on a filtrate-factor-free diet, but their weight-increase slows down to such an extent that statistically significant differences in weight-increases can be produced by supplements of filtrate factor in the ratio of 2 : 1, provided suitable response levels are chosen. This is an adequate basis for reasonably accurate vitamin assay. When, however, wheat starch replaces rice starch in our routine diet used for these tests, many of the animals show no slackening of growth after 4 weeks : discrimination between negative controls and animals receiving filtrate factor concentrate made from 32 gm. of fresh liver is seldom possible. With the rice starch-containing diet, groups of 3 animals are sufficient to detect the presence of such a concentrate in amounts made from only 8 gm. of liver. It would appear that the wheat starch we used had adsorbed or otherwise retained appreciable quantities of filtrate factor from the wheat berry.

We have no information about the effect of wheat starch on diets used for work on vitamin B_6 (adermin, 'eluate factor').

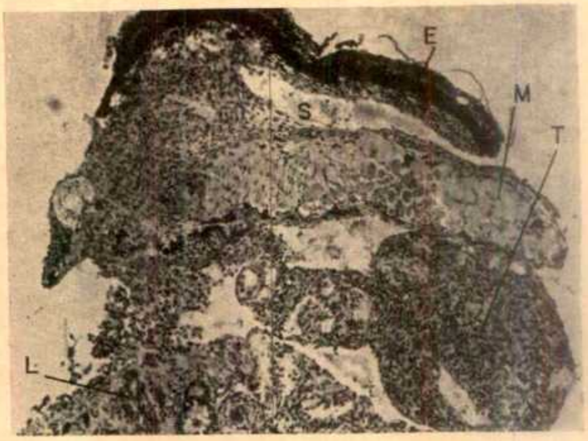
Tumour Induction in *Rana pipiens* Tadpoles

DURING the normal development of Amphibians the well-known 'fields' of organization operate to induce morphological differentiation[1]. Furthermore, adult Urodeles and larval Anurans are known to retain local fields which are active in the regeneration of parts[2]. Therefore, problems in abnormal growth may well be studied in those Amphibians which retain power of regeneration. One of the commonest present-day methods of experimentally producing abnormal growth is by means of carcinogenic substances, but apparently these substances have been little used for such studies in Amphibia. Recently, however, Koch, Schreiber and Schreiber[3] have induced tumours in adults of *Triton cristatis* and *Triton taeniatus* with 1 : 2 benzpyrene and with carcinogenic tar. The present report deals with induction experiments with *Rana pipiens* tadpoles using methylcholanthrene-choleic acid as the carcinogenic agent.

During February and March of 1939, 154 young tadpoles (20–30 mm. total length) were each injected subcutaneously near the base of the tail or behind the ear with about 0·2 mgm. of methylcholanthrene-choleic acid in crystalline form or in solution in lard. Healing occurred satisfactorily immediately after the operation, but during the subsequent three or four weeks, the skin above the injected mass perforated and the carcinogen was lost in most cases. 94 control tadpoles were injected with lard alone or with paraffin. All animals were reared at room temperature (c. 22°). Eleven experimental and four control tadpoles died and were autopsied before metamorphosis ; they had developed no growths. All of the surviving animals were autopsied during June, July and August of 1939 at about the time of metamorphosis. Thirty-nine of the ninety-four control tadpoles had retained the lard or paraffin ; no growths were found. Of the original 154 experimental tadpoles only 12 retained the injected mass and in 3 of these subcutaneous tumours had developed in tissue surrounding the carcinogen. In two cases (*MC* 512 and *MC* 711) observed 95 and 158 days after injection respectively the tumour remained localized, forming a firm, non-pigmented mass of tissue about 2 mm. × 1 mm. × 0·5 mm. in size in hosts of about 22 mm. body length. In the third case (*MC* 62–119 days) the induced tumour showed signs of malignancy. From the injection site it had spread subcutaneously, penetrating the body wall musculature and invading the posterior part of the left lung. At the time of autopsy it covered an area of 5 mm. × 1·8 mm. and was 1 mm. to 1·5 mm. thick. This is a large tumour in proportion to the size of the host—a metamorphosing tadpole of 18 mm. body length.



TUMOUR INDUCTION IN *Rana pipiens* TADPOLES (× 61).

The accompanying photograph illustrates some of the structural features of this growth. From the original site of injection in the loose subcutaneous tissue (*S*), the tumour has grown outward, spreading along the base of the dermis (*E*). Growing in the opposite direction, it has penetrated the body wall musculature (*M*), expanded as a sizable mass in the coelom (*T*) and invaded the lung wall (*L*). Histologically it appears to be a connective tissue tumour of mixed cell type. Cells are spindle-shaped, round, or intermediate ; also they are quite variable in size. Generally the cells are closely packed and give no evidence of differentiation.

One of the two localized tumours (*MC* 711) presents the same histological picture as that described above for *MC* 62. The second localized tumour (*MC* 512) was transplanted subcutaneously [illegible]to five tadpole hosts. Apparently the tumour tissue did not take in this small number of cases, for no abnormal growths have appeared in six months.

'Congenital' Copper Deposit in the Rat

THE striking increase in the copper concentration of the human liver, which begins during fœtal life and reaches its maximum at birth, has not yet been satisfactorily explained. Since the importance of copper as a catalyst for hæmoglobin formation is now conclusively proved for many higher animals, most authors consider the 'congenital copper deposit', too, to be connected with this function. Two hypotheses have been suggested in this respect: (*a*) copper is accumulated in the fœtal liver, because this is the chief site of blood formation during embryonic life; (*b*) copper is stored in the fœtal liver to compensate for the low copper content of milk during lactation, just as in the case of iron.

We have recently[1] raised some criticism against both views, which we see now supported by our new findings in the rat species.

Figures for liver copper in young animals are somewhat meagre. Cunningham[2] finds in seven species (bovine, sheep, pig, dog, guinea pig, rabbit and rat) similar conditions as in man, that is, highest values at birth and a rapid drop during the lactation period towards the low final level. Ramage[3], Wilkerson[4] and McFarlane and Milne[5], on the other hand, working with goat, pig and chick embryos respectively, observe the peak already during fœtal life and more or less low figures at birth.

During a study of iron, copper and hæmoglobin in white rats of various ages we were much surprised to find a marked increase of liver copper still after birth, the maximum not being reached before the 10–15th day of life (see accompanying table). Copper was determined by the dithiocarbamate method, non-hæmin iron by our hot pyrophosphate method[6], hæmoglobin spectro-colorimetrically.

The phenomenon occurred with great regularity in each of seven litters which had been followed from birth on during the first weeks of life; it contradicts the findings of Cunningham[2] who, however, has only examined one litter. The peak was always reached between the 10th and 15th day, nearly coinciding with the opening of the rat's eyes. It may be recalled here that the rat is born in a rather embryonic state of development, a fact which is also reflected in its red blood picture[7].

In contrast to the liver, the percentage of copper in the whole body was found to drop gradually from birth on, as already shown by Lindow *et al.*[8]

Histological examination, kindly carried out by Dr. H. Karplus, of some of the livers revealed no correlation between copper content and hæmopoietic activity of the liver; that was to be expected since this activity is highest during the early fœtal life—in birds and mammals—and has nearly disappeared at birth.

Our findings make hypothesis (*a*) untenable, and the same is true for the 'deposit' hypothesis (*b*), since the increase occurs just during lactation, and in spite of a general decrease in the body copper concentration.

Age (days)	Liver-Copper		Liver-Iron		Hæmoglobin	
	Average	Range	Average	Range	Average	Range
0–1	97 (13)	62–133	1790 (16)	1180–2650	12·1 (60)	7·3–15·3

* 30–34 days.

Copper, non-hæmin iron (mgm. per kgm. dry weight) and hæmoglobin (gm. %) in young rats. (Figures in brackets indicate number of animals.)

It appears to us that the rather dramatic accumulation of copper, occurring in different species at different times and paralleled by a similar increase in the copper content of young rapid-growing plant tissues, is not associated with the process of hæmoglobin formation but with growth and development, a view already suggested previously[9,10,11]. We are not yet prepared to say what particular process may be connected with the increase of liver copper; but the recent identification of several oxidases as copper proteins and the isolation of similar compounds from blood and liver[12] open many possibilities in this respect.

A detailed report of our experiments will be published elsewhere.

Use of Desiccated Chick Embryo in Tissue Culture Technique

ONE of the difficulties inherent in tissue culture technique is the necessity for a regular supply of chick embryo extract, without which serial subcultures cannot be maintained. When fresh 9–11 day embryos are used, it is almost impossible to avoid a waste of material as it is necessary to incubate more eggs than will probably be required in order to ensure a sufficient supply of embryos.

At the commencement of the War, we decided to try desiccated 9–11 day chick embryos as a source of active principle, and, since November 1939, have successfully maintained a variety of cultures of normal and malignant tissues on fowl plasma clot, to which this extract was added. By parallel experiments, in which fresh embryo was compared with desiccated embryo, it was found that extracts of the two were equally effective. The desiccate was recon[illegible]tuted by adding sterile distilled water up to the original volume. Aqueous extract prepared from such reconstituted material has better keeping qualities than fresh extract and can be used for ten days without apparent loss of efficacy.

In the dry state, the desiccate keeps without apparent loss of active principle for at least seven months; our desiccate has been kept in a refrigerator at 4° C., but this precaution may not be necessary. The desiccate can be prepared at short notice, and may be regarded as a standard reagent.

The following tissues have been grown progressively by this technique: (1) normal 17-day chick embryo heart muscle, for four weeks; (2) normal 18-day chick embryo fibroblasts, for four weeks; (3) Jensen rat sarcoma, for five weeks; after which, re-inoculated cultures grew in rats; (4) fowl-grown Fujinami filterable sarcoma, for 4–6 weeks, after which re-inoculated cultures grew in fowls; (5) *GRCH*/15 non-filterable sarcoma, for 4–6 weeks, after which re-inoculated cultures grew in some fowls.

The economy in time and material that is rendered possible by this technique recommends it, particularly under war conditions, as it is possible to incubate sufficient eggs when they are plentiful and when fertility is high to maintain cultures throughout the rest of the year. Thus, it is unnecessary to maintain an egg incubator in constant service. By using the infertile eggs (removed after twenty-four hours incubation) for cooking purposes, waste of material can be completely eliminated.

Vision and the Photochemistry of Visual Purple

Visual purple extracted from frog retinæ which is embedded in solid gelatine films ('artificial retina') reproduces on exposure to coloured light various phenomena of scotopic and photopic vision[1,2,3]. It is liable to 'general bleaching' or to 'colour selectivity' by photochemical processes. Both can be recorded by plotting the decrease of extinction against wave-length. If general bleaching occurs, the maximum of the graph (namely, at 530 mμ in the artificial retina) is independent of the spectral composition of the exposing light. In colour selectivity the maximum of the 'colour graph' coincides with the dominant wave-length of the coloured light for a normal trichromat. This forms the basis of an objective colorimetry[3].

The following conception accounts for the results obtained with the artificial retina[3]. Visual purple is a protein which is conjugated with a great number of caroteneic groups[4]. Its smooth absorption curve with a single maximum in the green is due to a mutual interaction of all the chromogenic groups. Monochromatic light of wave-length λ is supposed to produce an isomeric visual-purple-λ by a *cis-trans* transformation of a few double bonds[5]. After this change, the absorption curve of visual-purple-λ is still smooth with a slight decrease of extinction at λ, which accounts for the maximum of the colour graph at λ. Visual-purple-λ may be produced either by monochromatic light or by light of an appropriate spectral mixture. For example, visual-purple-589 may be formed by the *D*-lines, or by a mixture of monochromatic green and red, or by white light which has passed through a yellow filter, or a blue absorbing filter. By white light or by an appropriate mixture of various coloured lights (for example, complementary couples), visual purple is supposed to be decomposed into fragments, and general bleaching with its constant maximum at 530 mμ occurs. This also happens during a purely chemical after-effect in the dark. The two maxima of the colour graphs which are recorded in whitish coloured lights are therefore due to two different photochemical processes. Red light ($\lambda > 650$ mμ) decomposes visual purple on extended exposure and thus produces a secondary maximum of the colour graph at 530 mμ. Since the fragments are still colour selective from yellow to blue, it is probable that the original molecule is merely split into two parts. Extended exposure to blue light, on the other hand, is supposed to peel off photochemically the outer chromogenic groups of the molecule, leaving a residue which is found to be colour selective from red to green. The interpretation of the details of the experiments meets with no difficulties.

If the same processes occur in the living retina, it is obvious that vision is a chemical sense, with the sense of smell as its counterpart. The products of decomposition of the original visual purple stimulate the terminals of the optic nerve to produce a colourless sensation in scotopic vision, and a white sensation in photopic vision. The various isomeric visual-purple-λ stimulate coloured sensations with the dominant wave-length λ. Together with the products of decomposition they stimulate the mixed sensation of whitish hues. It is likely that colour blindness is due to a defect of the retinal tissues to build up the complete molecule of visual purple and that the synthesis does not proceed beyond the yellow-to-blue and red-to-green colour selective fragments.

From Hecht's experiments[6] it follows that the molecule of visual purple has the shape of a slightly oval particle. By assuming that the molecule is an ellipsoid with three unequal axes, the shortest axis would correspond to the strongest optical interaction of the chromogenic groups which makes them absorb red light. The longest axis would determine the absorption of blue, and the intermediate that of green light. The change of the molecule along these axes would stimulate the sensation of the three fundamental hues, and this conception would link the 'three-component' theory of colour vision with our photochemical hypothesis, which postulates an equivalence of all distinguishable hues.

Species Variation in the Insulin Content of Pancreas

Although the administration of a diabetogenic anterior pituitary extract diminishes the insulin content of the pancreas of the dog[1], treatment with similar extract increases the amount of insulin to be found in the pancreas of the rat[2]. In the course of an investigation into the influence of pituitary extract on the pancreatic insulin content of different species, we have observed substantial differences in the amount of insulin found in the pancreas of normal members of a number of species (see accompanying table). In particular, as the data in the table show, the insulin content of the normal guinea pig pancreas is very much lower than that of any of the other species we have examined, a result which was somewhat unexpected in view of the well-defined β cells to be found in the pancreatic islets of this species. These β cells contain chromaphil cytoplasmic granules which

INSULIN CONTENT OF PANCREAS OF DIFFERENT SPECIES.

Species	Weight of pancreas (gm./100 gm. body weight)	Insulin content of pancreas	
		Units/gm. pancreas	Units/100 gm. body weight
Chimpanzee	0·09	11·2	1·01
Dog	0·23	3·3	0·76
Cat	0·21	2·2[4]	0·47[4]
Rabbit	0·15 0·13	9·5 7·8[5]	1·42 1·17[5]
Guinea pig	0·37 0·31	0·08 0·23[5]	0·028 0·070[5]
Rat	0·48	1·3	0·62
Mouse	1·10	1·7	1·87

(Methods are those of Marks and Young (1939) unless otherwise indicated.)

are influenced by the blood sugar-level[3] and appear to be associated with the insulin-secreting mechanism.

When insulin was dissolved in an extract of guinea pig pancreas, only about 50 per cent of the expected activity could be found in the biological assay (mouse test), although the apparent activity of the insulin was not reduced if an acid aqueous solution of insulin was injected into one side of the mouse while the extract of guinea pig pancreas was simultaneously injected into the other. Substances in the extract therefore appear to interfere with the absorption of insulin from the subcutaneous tissues; but it is improbable that such an effect could entirely account for the fact that guinea pig pancreas appears to contain only about 1/15 the amount of insulin found in the pancreas of the rat.

Preliminary experiments have shown that the mouse resembles the rat in exhibiting a rise of pancreatic insulin content as the result of treatment with crude ox anterior pituitary extract, whereas the rabbit pancreas, like that of the dog, exhibits a fall in insulin content under similar conditions. With the rabbit, however, the fall was not so great as with the dog, a fact in keeping with the less consistent response of the rabbit to the diabetogenic action of a crude anterior lobe extract[6].

Concentrated Plasma in Histamine Shock

Best and Solandt[1] recently reported that the intravenous injection of pituitrin and concentrated serum produces beneficial effects on blood-pressure in dogs suffering from traumatic shock or histamine poisoning. We have studied the effects of various fluids in thirty cats injected with 5 mgm. of histamine per kgm., which in control experiments produces death within two hours. Animals receiving intravenously 10–25 c.c. per kgm. of concentrated plasma (concentrated to one half or one third its original volume) within ten minutes of the histamine injection survived for more than four hours and the blood pressure usually recovered to about normal level. Intravenous saline was ineffective. Normal plasma or gum-saline were also less satisfactory, generally producing only a short-lived rise of blood pressure. The administration of concentrated plasma may thus be of value in patients suffering from severe traumatic shock or other conditions associated with markedly increased capillary permeability.

Prevention of Seedling Blight in the Flax Crop

SEEDLING blight, caused by *Colletotrichum Lini* (Westerd.) Toch., is a disease of flax which is likely to assume greater importance should the cultivation of flax and the home-saving of seed become more widely and intensively practised. The parasite is seed-borne and damage caused by it to the crop would be largely prevented if a satisfactory method of seed disinfection, whereby the parasite is killed and the germination of the seed unimpaired, could be found.

In view of the possibility of seed-borne diseases of flax becoming of greater import, the problem of their prevention has occupied the attention of the Plant Disease Division of the Northern Ireland Ministry of Agriculture for the past two years. During this time rapid and accurate technique has been evolved for the examination of flax seed samples for seed-borne parasites, and a sorting test has been devised for the rapid discrimination between likely and unlikely seed dressings applied for the purpose of parasite extermination.

During the summer of 1939 a large number of chemical dressings were examined by the sorting test for the purpose of determining their efficiency, and among a range of materials submitted by the Imperial Chemical Industries, Ltd., an experimental product styled *R.D.* 7846 and containing tetramethylthiuram disulphide as its active constituent gave very promising results. One very pleasing feature of this product is that it is apparently non-poisonous. It is in the form of a finely divided powder and gave satisfactory results when applied to the seed at the rate of 3 gm. per 500 gm. (approximately 5 oz. per bushel of 54–56 lb.).

More extensive trials with the use of this material have been planned for 1940, and from preliminary results in the field which have already been obtained, the promise shown by the laboratory tests has been upheld. So far no phytocidal effects have been observed in the crops and the attack of seedling blight has been reduced to negligible proportions.

This statement should be regarded as of a preliminary nature and it merely records the possibility of *R.D.* 7846 being a suitable flax seed dressing for the prevention of seedling blight. It is not suggested that this fungicide is the most suitable for the prevention of other or all seed-borne diseases of flax, but owing to the possibility of the growing importance of seedling blight it is felt that this observation merits serious attention, especially at the present time.

RESEARCH ITEMS

Abnormalities of Speech and the Development of Language

A TENTATIVE classification of abnormalities of speech observed in children and defectives has been put forward by Leopold Stein, speech therapist of the Tavistock Clinic, London (*Brit. Med. J.*, June 1, 1940). In a baby of any race the first sounds observed are cries which correspond solely to emotional states of mind (fear, cold, hunger, etc.). These are at first mere reflex activities, and it is difficult to decide if they are articulate or not. As reflex activities, however, they represent a step in the recapitulation of phylogenetic development (animals' cries). Between the second and fifth week the primitive squall begins to be differentiated, among its special forms being the glottal stop, a primitive and very ancient symbolization related to all negative emotions such as fear, evinced, for example, in an advanced stage of stammering. Further, all children show a certain preference for nasal resonance in song and speech, like primitive peoples. In the babbling period there appears from about six months the so-called primitive sounds, the "Urlaute" (Russmaul, 1877), which it is assumed first appeared among mankind and from which developed the languages of to-day. It is richer in sounds than is required in after-life, while another characteristic is lallation, that is, the reiteration of syllables. They are not at first purposive, but become so. By comparison with a primitive language such as Hottentot, especially as regards primitive sounds such as 'clicks', and repetitions, this period appears also to be a recapitulation of one of the earliest phylogenetic periods of linguistic evolution. Next follows the period of linguistic babbling, when the child attempts to express wishes and ideas by imitation of the sound symbols of his surroundings, and when it has to adopt group modes of behaviour in this respect. The articulatory movements of the growing individual become canalized and conventionalized in the standard speech. In the study of abnormalities a child may develop idioglossia, that is, a language of its own; this is not a gibberish, but is found on study to be subject to certain laws of sound-changes, which may easily be compared with the phonetic changes in the historical development of languages.

Body Build

PROF. RAYMOND PEARL in seeking a formula for an index of body build (*Amer. J. Phys. Anthrop.*, 26, March 1940) points out that the importance of body build or bodily habitus in appraising the general biological constitution of the individual has long been recognized, more especially ever since Kretschmer (1925) emphatically and persistently directed attention to the correlations between habit of body and psychological and temperamental characteristics. A variety of proposals for a measure of bodily habitus has been made but none is completely ideal, since the human body is from a geometrical point of view a solid of an extremely complex shape, which it is difficult to express adequately by any simple numerical statement or formula. The biological root of the difficulty lies in the fact that changes in the size of the body from the pre-natal period to advancing age occur in all three of the fundamental reference planes of the body, length, breadth and thickness. Further correlation is low in degree and irregular. After surveying the various proposals and reviewing the desiderata, it is suggested that a bodily habitus index in use in the author's laboratory would seem to meet fairly most of the requirements. The formula in its most general form is: Habitus Index $= \frac{100\ (\text{chest girth} + \text{abdominal girth})}{\text{stature}}$. It is evident that the values of the index increase as we pass from extreme asthenic individuals, tall and 'skinny', who will have the lowest indexes, to the extreme pyknic individuals, short and stout, who will have the highest indexes. Secondly, the index is dimensionally homogeneous, involving only linear measurements. Further, all three of the dimensions are definitely located and are biologically significant. By actual trial on observed material this index proves to reflect in a sensitive manner differences between individuals in body build, and in the same individual differences consequent upon changes in body build with advancing age.

Insect Fauna of a Hornbill's Nest

IN the *Entomologists' Monthly Magazine* of May 1940, E. B. Britton, of the Department of Entomology, British Museum (Natural History), discusses the insects sent to him by R. E. Morgan from a nest of the silvery cheeked hornbill (*Bycanistes cristatus* Rüpp) at Amani, Tanganyika. Altogether some 438 individual insects were sent from the rotten wood forming the walls of the nest hole. There was no obvious dung or food debris present. The insects included 86 adults and 37 nymphs of the plant bug *Chilocoris laevicollis* (Fam. Cydnidæ). No explanation of the member of a phytophagus family breeding in the nest can be offered. Beetles of the family Carabidæ were represented by two examples of *Oecornis nidicola* gen. et sp. nov. and 15 larvæ possibly of the same species: 15 elaterid larvæ also occurred and 35 larvæ of a species of, or near to, Alphitobius (Tenebrionidæ). Lepidoptera was represented by 201 larvæ of the family Coleophoridæ. Also, there were 43 nymphs of a new species of Blattidæ and four acalypterate fly larvæ. It is noteworthy that at least seven of the eight species found in the nest were breeding there, and it is concluded that the thoroughly sanitary state of the nest must owe much to their scavenging activities.

Echinoderms from the John Murray Expedition

Two recent reports deal with the Regular Echinoidea and the Ophiuroidea respectively (John Murray Expedition 1933–34, *Sci. Rep.*, 6, No. 1. "Report on the Echinoidea of the Murray Expedition", Part 1. By Th. Mortensen; and 6, No. 2. "Ophiuroidea". By Hubert Lyman Clark. British Museum (Natural History), 1939). There are 35 species of regular Echinoidea collected by the Expedition, less than those obtained by the *Investigator* (50 species), but with regard to the Cidarids it has done even better, for out of 12 species, 5 are new, one representing a new genus. Moreover, two of these, *Cidaris mabahissæ* and *Lissocidaris fusca*, are of great zoo-geographical interest as they belong to the sub-family Cidarina, hitherto only known from the Atlantic. *Goniocidaris indica* is also a very interesting discovery as the genus, so richly developed in the Japanese-Malayan-Australian region, is not otherwise represented in the Indian Ocean. A discussion of the zoo-geographical problems will be included in Part 2 of this report. The Ophiuroids form a splendid collection from the North West Indian Ocean. It is very rich in genera and species, there being six new genera out of 42 obtained and out of 102 species one third are new. All are very distinct forms. The numerous illustrations are very clearly drawn and show the essential features. From the study of the *Mabahiss* material it is shown that the ophiuran fauna of the Arabian Sea and adjoining coasts has undoubtedly originated from the East Indian Region but has not yet developed nearly so rich a littoral group and there is a markedly large proportion of endemic species.

Garden Plants of the Future

MANY plants of potential garden beauty lie in static conservation within herbaria. F. Kingdon Ward, though himself responsible for numerous exsiccata, has made a survey of such conservatories in order to discover horticulturally deserving plants which have not yet been aligned with garden practice. A few of these have recently been described (*Roy. Hort. Soc. J.*, 65, Pt. 5; May 1940). *Vaccinium modestum, Laccopetalum giganteum, Arctomecon californicum,* two species of *Veronica, Rhododendron Devriesianum, Gentiana setulifolia* and *Limonium insigne* are but a few botanical examples of world-wide origin, which have not yet enjoyed the care of the cultivator. Captain Kingdon Ward's descriptions, however, show that gardens would indeed benefit from their introduction, and this experimental invasion of 'botanical mausoleums' might well be extended.

Apomixis in Crepis

G. L. Stebbins and E. B. Babcock (*J. Hered.*, 30, 519–529; 1940) and G. L. Stebbins and J. A. Jenkins (*Genetica*, 21, 191–224; 1939) describe the behaviour of several North American species of Crepis. These species are polymorphic, have variable and high chromosome numbers, and are apomictic. Within the group of species studied, only seven were diploid and sexual and considerably restricted in geographic range. The polyploid forms either simulate the diploid form very closely, and are presumed to be auto-polyploids, or combine the characteristics of two or more diploid forms. The apomictic forms are either obligate or facultative, and reproduce by somatic apospory followed by parthenogenesis as in Hieracium (Rosenberg). The origin and spread of the polyploid forms are described. It is suggested that apomixis accompanies hybridization and polyploidy, but is not caused by either. The origin of apomixis is suggested to be related to genetical or factorial causes. The apomictic forms sometimes produce progeny by sexual means, and thus secondary types are evolved. As these authors and Banta (*Proc. Gen. Soc. Amer.*, 1939) point out, the apomictic-amphimictic life-cycle greatly favours the rapid spread of variants. Hence it is found that there is great polymorphism as one leaves the region of the diploid progenitors. Occasional crossing between an allo-polyploid and a third diploid species will also increase the variation.

Male Sterility in Hebe

IN a population of 2,200 plants of *Hebe traversi* at Cass, New Zealand, 3·5 per cent of the plants were found to be pollen sterile. O. H. Frankel (*J. Genet.*, 40, 170–184; 1940) also found wild plants of other species of Hebe to be pollen sterile. Cytological study showed that the chromosomes of male sterile *H. parviflora* and *H. subalpina* collapse into an amorphous mass following pachytene. In *H. salicifolia* var. *communis* all stages are normal until telophase II, but no tetrads were seen. In *H. leiophylla* × *H. salicifolia* and in *H. traversi* pollen grains degenerate very soon after formation and before the cell walls thicken, whilst in *H. Townsoni* an upset of timing of meiosis in the anther is present together with signs of collapse of the pollen grains. It is suggested that some major physiological disturbance affects the loculus at a time characteristic of the particular male sterile form.

Irregular Flowers in Phlox

J. P. KELLY (*J. Hered.*, 31, 169–171; 1940) bred from an individual of Phlox the flowers of which lacked one or more petals. The characteristic was inherited, but great fluctuation in the proportion of irregular flowers was found. In an F_1 hybrid between regular and irregular flowered plants, 147 were regular and 10 slightly irregular. The F_2 segregated 808 regular : 197 irregular. Other data show that the fluctuation in irregularity is environmental in origin.

Core Disease in the Apple

H. P. BELL has published an interesting note on the susceptibility of the Gravenstein apple to core disease (*Canadian J. Res.*, 18, No. 3; 1940). Harrison has previously suggested that the "constitutional weakness of the calyx end" was responsible for the prevalence of this trouble in the variety, and Prof. Bell's observations confirm this suggestion. The carpellary cavities are usually closed from the stylar cavities by solid tissue in the intervening region, which might be described as at the upper level of the calyx tube. In the Gravenstein, however, cavities in the radial stylar extensions continue to penetrate very deeply into this tissue, much more deeply than in other varieties studied. Thus this tissue organization is structurally weaker at this calyx end of the apple, and radial fissures may easily develop and facilitate the entry of disease to the carpellary core.

Radio Echoes and Fading

J. A. Pierce and H. R. Mimno (*Phys. Rev.*, 57, 95) point out that the records of signals reflected vertically by the ionosphere sometimes show an anomalous distribution of intensity among the successive reflections; for example, highly multiple reflections may be as strong as, or stronger than, the first two or three reflections. This condition may persist for ten minutes or so at a time, and the authors explain it by supposing that the ionospheric layers show local curvature which focusses the waves on the receiver after a certain number of reflections. These effects are only observed when transmitter and receiver are close together, and have no effects in normal radio communication. It is probable, however, that focussing by reason of changes of curvature in the F layer may affect communication over distances comparable with the radii of curvature, of the order of thousands of kilometres, and the authors discuss cases of slow cyclic fading in trans-Atlantic short-wave signalling which may be explained in this way. Sunrise must be associated with considerable slope and curvature of the surface of the ionospheric layers, and in fact the focussing phenomena have been observed at this time. A mechanism is indicated which leads to the reflection of rays back to the transmitter by a complicated path at such a region of curvature, and may lead to the production of echoes of very long delay of the order 0·1 sec. A similar suggestion of local irregularities was put forward some years ago by G. R. Toshniwal, B. D. Pant, R. R. Bajpai and B. K. Verma (*Proc. Nat. Acad. Sci., India*, 6, 161 ; 1936).

Field Produced by a Linear Radiator

A paper by F. M. Colebrook, of the National Physical Laboratory, has been communicated to the Institution of Electrical Engineers (*Journal*, Feb. 1940), on the electric and magnetic fields of a linear radiator carrying a progressive wave. The vector- and scalar-potential method of calculating electric and magnetic fields is applied to a straight conductor carrying a progressive wave of current. The author proves that unless the conductor is assumed to be terminated by charges which satisfy the condition of electrical continuity at the ends, the calculated field has an anomalous and impossible character. Such charges need not be included in the case of closed circuits of conductors carrying progressive waves. He confirms this by analysing in a special case the mutual cancellation of the anomalous features. It is pointed out that a linear progressive wave radiator has only one axis of symmetry, which is that of the radiator itself. This differs from a standing wave radiator which is symmetrical about the equatorial plane. Analysis thus confirms the asymmetry of the field from a progressive wave radiator. The field system associated with a progressive wave of current is regarded as a more fundamental conception than that due to a standing wave, since any standing wave system of currents is resolvable into positive and negative travelling waves. This feature is illustrated by the synthesis of the travelling wave fields into the known form for a dipole standing wave radiator. The radiation resistance of a progressive wave radiator is calculated by Pistolkoro's method, and is shown to be equal to that for a standing wave radiator when the length of the radiator is an integral number of half wave-lengths.

Electron Microscope

The RCA Manufacturing Co., Camden, N.J., U.S.A., announces the production of a new electron microscope developed in their research laboratories by Drs. L. Marton and V. K. Zworykin. The instrument, like that described by Martin, Whelpton and Parnum (*J. Sci. Inst.*, 14, 14 ; 1937), employs the magnetic lenses, the optical equivalents of a condenser, objective and projector. The intermediate, or first-stage image, is produced by the objective at a magnification of 100 diameters. This image is subjected to a further magnification of 250 by the projector lens, which throws the final image at a magnification of 25,000 on to a fluorescent screen for direct observation or on to a photographic plate. The quality of the photographic record of the final image is such that a further optical enlargement of 4 diameters may be used, giving a total overall useful magnification of 100,000 diameters. The technique of preparing specimens for examination has been carried to a stage where the instrument is ready for use in a research laboratory. Examples of the application of a similar instrument to biological investigation have recently been given by von Ardenne (*Naturwiss.*, 8, 113–127 ; Feb. 23, 1940) who has photographed such objects as diatoms, viruses and bacteria at magnifications up to 100,000. The development of the instrument has opened up a new field to direct observation hitherto far beyond the resolving power of the optical microscope. The size and shape of smoke particles and the changes during the reaction of small particles with a gas are susceptible to direct visual observation. The use of the instrument promises to yield much new knowledge about particles of colloidal dimensions.

Energy of Gaseous Molecules

The calculation of the fraction of the molecules in a gas which possess energy above a specified amount is simple when motion in only two directions is considered but becomes difficult when three directions are considered. Hence in many cases the simple form for motion in two dimensions has been used in cases where three dimensions are involved. A. H. Heatley (*Canadian J. Research*, 18, 123 ; 1940) has given a table of a function from which the ratio, v, of the fraction N_1/N (N is total number of molecules, N_1 is number of molecules possessing energy greater than E for the two-dimensional case ($N_1/N = e^{-E/RT}$) to the ratio for the three-dimensional case) can be calculated. This ratio is equal to $[2x^2 + L(x)]/x\pi^{1/2}$ where $x^2 = E/RT$ and $L(x)$ is a tabulated function, the relations of which to the error function complement and other functions are given. It is shown that the ratio v changes rather slowly as E/RT changes :

E/RT	0	1	4	9	16	25	36	49
v	1·00	1·56	2·51	3·56	4·65	5·73	6·86	7·98

Properties of 3 : 6-Anhydrogalactose

The transformation of an α-methylglycoside or a β-methylglycoside into an equilibrium mixture of the two forms may be effected by means of methyl-alcoholic hydrogen chloride, and it is usually accepted that this transformation involves the intermediate formation of the free sugar. W. N. Haworth, J. Jackson and F. Smith (*J. Chem. Soc.*, 620 ; 1940) have now described the syntheses of 3 : 6-anhydro-α and β-methylgalactopyranosides and various methylated derivatives. Liquid 2 : 4-dimethyl 3 : 6-anhydro-α-methylgalactopyranoside can be directly transformed into crystalline 2 : 4-dimethyl 3 : 6-anhydro-β-methylgalactopyranoside by small amounts of hydrogen chloride in air, hydrogen bromide in air, ethereal hydrogen chloride, ethyl-alcoholic hydrogen chloride and methyl-alcoholic hydrogen chloride. The direct isomerization of α to β also occurs spontaneously when the α-form is kept for several months. None of these methods appears to involve the intermediate formation of a free reducing group. With excess of methyl-alcoholic hydrogen chloride both the α- and β-form of 2 : 4-dimethyl 3 : 6-anhydromethylgalactopyranoside, which have strained structures, yield the relatively strainless 2 : 4-dimethyl 3 : 6-anhydrogalactose dimethylacetal. Hydrogen chloride or hydrogen bromide effects the removal from this of the elements of methyl alcohol, and 2 : 4-dimethyl 3 : 6-anhydro-β-methylgalactopyranoside is produced. It is suggested that the steric effect of the stable 5-membered 3 : 6-anhydro-ring is responsible for some of the peculiar properties of 3 : 6-anhydrogalactose and its derivatives.

AGEING OF POPULATIONS

PROF. RAYMOND PEARL'S presidential address at the centenary celebrations of the American Statistical Association on December 29, 1939 (*J. Amer. Statist. Assoc.*, 35, 2; 1940), points out that populations indubitably age with time, and as a relevant example compares certain aspects of the population of the United States one hundred years ago and the population of to-day in those areas which formed part of the States one hundred years ago.

Notwithstanding the partiality of poets and other writers for the seven stages of man's life, biologically the life-cycle of any mammal falls into three stages, and three stages only, which have epistemonic significance. These are pre-reproductive, reproductive, and post-reproductive. In man the pre-reproductive stage includes infancy and the major part of growth. The reproductive phase is *also* the period of full vigour in all the manifold ways that the human engine uses to let off steam. The post-reproductive phase is *also* the period of senescence, and of the ripened wisdom that only the experience of living a long time can bring. Mostly these matters biologically are *also* secondary to the basic business of life; one of them, however, is of first-rate importance, especially in the human animal, namely, that people in the reproductive phase have to do the work not only to get their own livings, but also the livings of the young and the major part of the livings of the old in the post-reproductive phase. This puts a heavy burden of work on the shoulders of a moiety of every human population that we know anything about.

From this consideration arises a threefold age classification of 0–14 years, 15–49 years, and 50 years and above, allocating the population in substantial accord with the fundamental biological divisions of each individual human being's life-cycle from birth to death. About 50 per cent of all populations, it has been noted, fall into the 15–49 class, but in the other two classes the numbers vary more widely and in a compensatory way. Thus a population like that of India in 1931 had 39·9 per cent in the pre-reproductive phase, 50·4 per cent in the reproductive phase, and only 9·7 per cent in the post-reproductive phase. In the same year, by way of contrast, the population of France had only 22·9 per cent in the pre-reproductive phase, abou[illegible] 51·4 in the reproductive phase, and almost three times as great a proportion, 25·7 per cent, in the post-reproductive phase. Biologically the two populations are deeply differentiated.

It is clear that the status of any population at a given moment relative to the proportions of its component members, falling in the three biological phases of the life-cycle, may have an important and direct bearing upon the aggregate or composite behaviour of that population and upon the probable course and outcome of any enterprises upon which it may embark as a whole. Of all the forms of aggregate behaviour in which a population may become involved, war is one of the most significant as well as dreadful. Comparing the populations of the chief protagonists in World War I of 1914 and World War II of 1939, taking Germany and Austria in 1914 as opposed to France, England and Wales, Scotland and Belgium, but omitting Russia for certain reasons, as well as outlying parts of the British Empire, on the figures of 1910–11, Germany and Austria had resources of upwards of 64 million persons, of whom approximately 33·5 per cent were in the pre-reproductive phase, 50·8 workers of the reproductive phase, upon whom fell the burden of fighting and producing goods for the troops and civilian population, and 15·7 were over 50 years of age; or taking male population only, 34·1 per cent, 51·3 per cent and 14·7 per cent respectively. Among the Allies the corresponding figures were a total population of 87·5 millions, of whom 52·2 per cent fell in the fighter-worker class, representing an actual advantage of nearly 3 million persons. In the under 15 phase were 28·5 per cent, and over 50 years about 19·3 per cent. Taking male population only the Allies numbered upwards of 48 millions against 32 millions for Germany and Austria, a relative advantage of 34 per cent. Of its components 52·4 per cent fell in the fighter-worker phase as against 51·3 in the German controlled population resources.

At the outbreak of World War II, the Allies had total population resources of both sexes of 87 million persons, of whom more than one quarter (as against 19 per cent in 1914) were of post-reproductive age. Further, instead of 52·2 per cent of fighter-workers, there are only 51·3 per cent in this phase. Finally, instead of 28·5 per cent of youngsters coming of age there are only 23·6 per cent.

The population resources controlled by Germany (including Czechoslovakia) in September 1939 present a different picture. She has a total of approximately 90 millions to draw upon. Of its component members 53·7 per cent, as against the Allies 51·3 per cent, were in the fighter-worker phase, representing an advantage of more than 3·6 millions of persons, of whom a little fewer than half are males, while there are only 22·4 semi-dependent old folks as against the Allies 25·2 per cent, while of youngsters there are 23·8 as against the Allies 23·6 per cent. It is plain that so far as the population aspects of war are concerned, the absolute and relative advantages and disadvantages accruing from that source have become reversed in the quarter of a century separating these two great conflicts. Falling birth-rates on one side and rising birth-rates on the other have been in the main responsible.

Prof. Pearl went on to analyse in similar manner the white population statistics for thirty political subdivisions of the United States in 1840 and 1940, and arrived at the main conclusion that while the old folks on one hand and the youngsters on the other are "ganging up" on the half of the population [illegible]at does the work, pays the bills and taxes, and in cold fact earns the living for all, whereas in 1840 each 1,000 workers had 1,084 other persons, younger and older, to take care of, in 1930 each 1,000 of the 44,134,796 workers supported only 880 persons besides themselves. Biologically this appears to be a striking example of *adaptation* of the human species, *qua* species. The current use of such devices as contraception (or, for that matter, capitalism or communism) as adaptive procedures to ease the burden of ageing populations may in the long run be the moral equivalent of curing a toothache by the effective but disastrous technique of cutting off the patient's head. It is no good making life easier if there is no one to live it.

IRRIGATION RESEARCH IN THE PUNJAB

A MODERN aspect of irrigation has been given prominence by the recent publication of the report of the Punjab Irrigation Research Institute for the year ending April 1938.[*]

The report is a record of considerable activity and success in dealing with the great direct and indirect problems associated with the large-scale irrigation of an alluvial countryside. During the year there were added to the facilities of the Institute a new Hydraulic Laboratory and a River Research Station at Malikpur, but even with these the pressure of the demand is unabated, for the growing recognition of the importance of soil studies has resulted in an increased volume of work.

The staff of the Institute is divided into seven different sections to deal with the several classes into which its work may be assorted. In the Chemical Section, perhaps the most important investigation was that on the reduction by chemical means of seepage losses from canals, which has now reached the field stage. Here the result of treating the bed of the Awagat Distributary with a lining of soil impregnated with sodium chloride was to reduce the seepage by 2·3 cusecs, and this at a cost which it is calculated will be paid for by the additional revenue from the water saved over a period of three years. This Section has also been investigating the movement of salts in the soil profile, which in the Punjab alluvium consists of a shallow soil crust overlying sand. With a rising water-table the salts move towards the surface and form an accumulation ; from intensive examination of a small area it was determined that there is no lateral movement of the salts and their rise at any point depends mainly on local characteristics and on the factors causing the rise. The work in the standardization of methods has resulted in a simple procedure for estimating total sulphides in soils and irrigation waters and in the determination of the isohydric pH value of soils, both of which are explained in the report.

The chief study which has engaged the Physics Section was one on tube wells in model, and was directed towards determining the factors which influence discharge. The conclusions pointed to are threefold, it being found that, subject to certain provisos, the yield is generally proportional to the draw-down and increases very slowly with increase in the diameter of the strainer, while it can also be increased by shrouding. Other investigations in this Section were concerned with the problem of seepage from canals, with the transmission constant of sands and with silt in relation to regime conditions. Experiments were begun in the Laboratory to examine the capillary rise in soils, and particulars of the method and apparatus in use are given.

Relationships between the bed silt and the hydraulic elements of channels have been investigated by the Statistical Section, and the empirical results obtained have already been found useful in the running of old channels and the design of new ones. Although they are not put forward as of general application, the suggestion is made that they should be tested on canal systems outside the Punjab. The most important work of the Hydraulic Section was provided by the Haveli Project in the reconditioning of works and river training operations. Laboratory investigations were made in order to get a design for the Trummu Weir which would give maximum coefficient of discharge, and the falls to be constructed on the canals have been exhaustively studied.

At the River Research Station at Malikpur a model was made of the Rivers Chenab and Jhelum at their confluence, and the work done on this has led to precautions being taken which will reduce to a minimum difficulties which have been met in earlier constructions of this nature. An interesting point arising from the Land Reclamation Section's report is the tendency of cotton land to deteriorate, while that irrigated for rice gives a more permanent form of reclamation.

---

THE SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES

IN the account of the Congress of the South-Eastern Union of Scientific Societies held at St. Alba[illegible] last year, printed in NATURE of July 8, 1939, it was suggested that this year the usual five-day Congress might be held in Cambridge and, as supplementary to the main annual Congress, single-day meetings might also be arranged to help local societies in centres too small to justify selection as a meeting place. The effect of war conditions, however, has ruled out Cambridge for the present. Following the precedents set in 1917 and 1918, therefore, for general convenience the abbreviated Congress was held in the rooms of the Linnean Society in London on June 12.

In the morning the Sections held their business meetings, independently, each being followed by an address and discussion. The addresses will appear later in an abbreviated volume of the *South-Eastern Naturalist and Antiquary* (vol. 45) and were as follows : archæological address on "Medieval Towns" by Mr. G. E. Chambers ; botanical address on "Seaweeds and their Uses" by Dr. E. M. Delf ; geological address on "Hints on Geological Mapping" by Dr. R. L. Sherlock ; and, in the afternoon, zoological address on "Waterfowl" by Mr. D. Seth-Smith.

The new president of the Union, Dr. R. R. Marett, Rector of Exeter College, Oxford, delivered his address on "Realism and Idealism in the Study of Man". Anyone who has read Prof. H. L. Hawkins's 1938 Alexander Pedler lecture on "Humanity in Geological Perspective", given at the Worthing Congress, will recognize that both treat of the same general theme, but from different angles, and arrive at the same conclusions. Dr. Marett's main point was that a philosophy and a science of man must come to terms; in other words, that any doctrine of human perfectibility should have regard for man's place in Nature as the anthropologist seeks to determine it. The conditions of survival must be observed if a given people, or the race as a whole, is not to be improved clean off this planet.

True, the human species for the moment enjoys a biological dominance scarcely challenged unless it be by the bacteria; so that man's greatest foe is, roundly speaking, himself. Even so, it would not take the race long to breed up to the extreme limit of bare sustenance; and to-day those who desire not merely to live but to live well, in short, the representatives of the higher culture, are elbowing entire peoples of backward culture out of existence. A survey of the world's potential food supply shows that mankind has already exhausted much of its heritage by failure to attend to the principles of soil conservation; nor can all the brilliancy of city life atone for neglect of the land, since a city population, despite the diversity of its arts, is somewhat overcrowded and is too near the hunger line to offer any security to the improvident. Physical anthropology has no knowledge of any chosen people, or of racial limitations of intelligence, that would prevent the exchange of ideas between men whose minds, like their tongues, have acquired a catholic function.

A bulletin (No. 75) issued for the Congress outlined the research work being carried out by the affiliated societies independently: it includes archæological excavations at Highdown Hill, Sussex, the application of science to animal welfare, ecological research at Limpsfield Common, observation of insect immigration, and the preparation of various lists of local flora and fauna upon the plan suggested by the Association for the Study of Systematics in Relation to General Biology. Certain centres where future congresses are likely to be held are preparing the material for the issue of local survey volumes, on the plan advocated by the British Association, in a uniform edition of which those for Hastings and Worthing have already been published under the title "A Survey of Times Past and Present" (3s. 6d. net).

The annual report of the Insect Immigration Committee shows that by placing more reliance upon individuals keeping daily observation on schedules issued in each county, it will be possible to continue to collect records despite war conditions. The year 1939 was remarkable for the immigration of Large and Small White butterflies in southern England the larvæ of which ravaged market gardens more extensively than for the past twenty years; but as so large a percentage of the larvæ were parasitized, pest conditions are not expected to result this year. In France some 10 per cent damage was done by Painted Lady butterflies to globe artichoke plantations, but heavy rains practically wiped out the larvæ and only 4,500 butterflies of this species were recorded in the British Isles. Before May 1, 1940, the unusually large number of ninety Painted Lady butterflies were recorded, which either indicates a very early immigration from warmer climes or that the species can tolerate a dry winter, however cold, by hibernation like our Small Tortoiseshell.

The Congress hopes to meet next year in Brighton.

T. D.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER IN ELECTRICAL ENGINEERING—The Registrar, College of Technology, Manchester (July 9).

ASSISTANT LECTURER IN ENGINEERING (MECHANICAL)—The Registrar, The University, Manchester 13 (July 13).

WORKSHOP INSTRUCTOR FOR ENGINEERING WORKSHOP PRACTICE AND WOODWORK, and a GRADUATE IN ENGINEERING OR SCIENCE TO TEACH MATHEMATICS AND SCIENCE, at the Schofield Technical Institute, Mexborough—The Secretary to the Managers, West Riding of Yorkshire Education Department, Education Office, Mexborough (July 13).

ASSISTANT TO THE ADVISORY OFFICER IN ANIMAL HUSBANDRY—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (July 15).

PROFESSOR OF VETERINARY SURGERY, OBSTETRICS AND ANIMAL HUSBANDRY at the Veterinary College, Ballsbridge, Dublin—The Secretary, Civil Service Commission, 45, Upper O'Connell Street, Dublin (July 30).

PROFESSOR OF OBSTETRICS in the University of Sydney—The Secretary, Universities of the British Empire, 88a Gower Street, W.C.1 (September 30).

DIRECTOR OF SOCIAL STUDIES—The Registrar, University of Sydney, Sydney, New South Wales, Australia (September 30).

GRADUATE LECTURER IN MECHANICAL ENGINEERING at the Royal Technical College, Salford—The Acting Director of Education, Education Office, Chapel Street, Salford 3.

LECTURER (GRADE II) IN THE FACULTY OF ENGINEERING—The Secretary, University College, Gower Street, W.C.1.

THE FUNCTION OF THE PRESS

AN important declaration of policy was made by the Lord Privy Seal, Mr. Attlee, on July 3, in answer to a Parliamentary question regarding the liberty of the Press. He said:

"The policy of the Government is to interfere as little as possible with the liberties of the Press to express freely their opinions and comments on the conduct of the war or on supposed peace overtures." He pointed out, however, that information useful to the enemy can be included in statements that appear to be opinion only, and that the Government was not prepared to undertake not to interfere with such statements.

The question and answer came as a sequel to a number of comments in the daily Press which seemed to indicate that an extension of the present method or scope of censorship was imminent, and they will reassure public opinion to some extent. In these critical days, it cannot be denied that a measure of censorship is necessary. On the other hand, one of the fundamental issues of the conflict is the right to freedom of the Press, freedom of speech and thought for the individual. How can these contradictions be resolved? Under the present system, editors of journals are responsible for seeing that nothing likely to be of use to the enemy is published by them. When doubt arises, the matter can be submitted to official censorship. On the whole, the method has worked well. The Press in Great Britain has grown up in an atmosphere of free discussion, and it recognizes the need for the present restrictions in the interests of the welfare of the country and the cause to which we are committed. It is not prepared, however, to accept interference with its long-established function of criticism of policy and action.

So far as the lay Press is concerned, the question of censorship is concerned mainly with the publication of news in letterpress and pictures of events, of weather conditions and similar information, much of which, if not carefully weighed, would be of considerable value to the enemy. The technical Press is somewhat differently affected. Among other matters, a strict watch has to be kept so that information as to the location of new industries is not disclosed, and industrial developments or progress must obviously be treated with caution.

In NATURE, the problem is different again. All scientific advances can be regarded as possibly of service to the enemy; but to follow this line of action literally would be tantamount to suppressing the diffusion of knowledge. In consequence, all communications submitted for publication in the correspondence columns of NATURE are examined carefully from this point of view and in the light of knowledge of current events; and the Editors have not hesitated to take further advice when an element of doubt has seemed to be present. Many contributors are themselves doing work of national importance, and they should know at once whether their results ought or ought not to be published. On the other hand, many others whose duty it is to carry on their normal work, will naturally wish to inform their fellows of results obtained. They should then ask themselves whether their work is likely to have practical applications which might be of service to the enemy.

Another function of NATURE is to keep scientific workers and others informed by means of descriptive articles of the progress made in selected subjects. Here again the needs of the times have to be borne in mind, and in addition to surveys of progress, NATURE is publishing articles dealing with topics of immediate importance, such as those now appearing on various aspects of the utilization of waste materials.

It is, however, in the matter of leading articles and critical notes that NATURE is perhaps most deeply concerned in the freedom of the Press. A rigidly controlled Press is a characteristic feature of totalitarian rule, echoing with fulsome monotony the official view. It is equally characteristic of the democratic system that officialdom is open to criticism, out of which comes further progress. This is the particular 'freedom' for which a journal such as NATURE must stand; not the freedom to make malicious attacks on the policy of Government, but the freedom to make constructive criticism in order to promote the cause we all have at heart. It is a hardly won privilege, which we have used, and shall continue to use, with a keen sense of responsibility.

SCIENTIFIC METHOD IN ADMINISTRATION

THE willingness and cheerfulness with which the whole nation has accepted the drastic restrictions now being placed on civilian supplies and the use by the Minister of Labour and National Service of the wide powers of control which he now possesses over labour and industry, are a measure of the determination of the British people to continue the struggle for freedom in the world. The magnificent response of labour to Mr. Bevin's appeal indeed shows that the people of Great Britain have shed any lingering illusions as to the magnitude of the effort demanded of them all, but it would be unfair to place all the responsibility for this apparent change on the dramatic swiftness with which the tide of war has rolled towards our own shores since the invasion of the Low Countries and France. Part at least of the response is due to a leadership for which many had been impatiently waiting for months.

The changes and effort involved in the transference from a peace-time to a war economy have been reviewed in a number of admirable broadsheets issued by P E P (Political and Economic Planning), notably under the titles "The Home Front" and "Industrial Man Power", and the second of these broadsheets reviewed the position up to the recent change in Government. Since then we have moved much nearer to a full war economy. It has become a matter of life and death that the habits and customs of a *laisser-faire* society should be abandoned, and the economic and social implications of modern warfare be fully recognized. Just as the new order gives the Minister of Labour full and drastic powers over every man and woman in the land to ensure the most effective use of the nation's resources of man- or woman-power, so the new rationing order limiting supplies to home consumers, issued by the Board of Trade, supplies the power to check any who are still reluctant to curb their own private requirements at a time of national need.

Fully as significant, however, as the evidence that these developments afford that the Government possesses a definite economic policy and the vision and vigour to elaborate it into the detail required, is the fact that they have been gladly accepted by a nation which was indeed largely impatient for them. For that, as we have said, credit must be given to wise and imaginative leadership, alive to the necessity of education in a constructive enterprise of this magnitude. By taking the people into its confidence, the Government kindled their imagination and paved the way for the magnificent response which in due course will enable us to wrest the initiative from the enemy, and bring final success to our efforts.

Neglect of such educational work has been an important factor in the failure of the earlier evacuation schemes for school children, and there are still many fields such as rationing, the restriction of private purchases, and civil defence, in which educational work is still required. This may well be one of the directions in which the Ministry of Information may make important contributions. With such education, there must go the utmost diligence to see that the full purpose of the new efforts is not impeded by vested or private interest of any kind. Nothing can be tolerated which is liable to endanger confidence in the impartiality or integrity of our leadership; this has special significance in considering the restriction of certain forms of sport or pleasure or of the production of some types of foodstuffs or beverages.

We are none the less entitled to the conclusion that in these difficult and anxious days, we have now a Government which is in advance—even if only a little—of public opinion, and not far behind it in its ideas of the sacrifices and effort that must be made, and made at once. This fact and the opportunities thereby opened up constitute at least one reason for hope in a desperate situation. If our present intense effort is wisely and effectively organized, we can gain the time and opportunity, as the full power of our resources is brought into play, to deal with those many interlocked problems not merely of a war economy but also of reconstruction after the war. We have at least come within sight of leadership of a quality competent not merely to organize effectively our resources for war but also to use wisely the immense opportunities which the catastrophe of war gives us of overthrowing obstacles which have impeded the development of society in time of peace.

It is well that this question of reconstruction should remain in our minds even at this critical hour, for many of the problems with which we are now dealing urgently are vitally related to them, and it may well be that the solutions to some of our longer range war problems and those of reconstruction may be found on similar lines. The immediate problems involved in the most efficient use of our man-power have their bearing on the unemployment problem, the magnitude of which after the War may well be determined by the lines on which our labour problems are now handled. Measures affecting the mobility of labour, its training in new types of skill, the neglect or encouragement of technical education, and the care taken in regard to training in safety methods or the safeguarding of health, whether in respect of hours of work, or factory or workshop conditions such as lighting, ventilation or the like, may have as a significant influence on the morale and adaptability of the industrial population after the War as on the efficiency of our immediate war effort.

That the Ministry of Labour has taken over from the Home Office the whole administration of the factory, including the health and welfare provisions, and that the Factory Department of the Home Office is now incorporated for the duration of the War in a new department of the Ministry of Labour called the Factory and Welfare Department, are signs that concern with the short-range problems of immediate intensive production will not lead to those of a long-range policy being overlooked. Steps have also been taken, at long last, to facilitate the development of a food policy based on scientific knowledge and control ; in no other field could a scientific policy have more far-reaching and beneficial effects both after as well as during the War. The building industry and the shipping industry are two further examples where policy or machinery established during war-time must have far-reaching repercussions on recovery.

If there are thus signs not only of energy but also of the forward-looking mind in the leadership of the Government, there is one element in the situation which has given rise to some misgivings. In his volume "Security : Can we Retrieve It ?" published shortly before the War, Sir Arthur Salter directs attention to the desirability of strengthening the Civil Service by reinforcing its personnel, at the top with leading men in industry and science, and throughout its ranks with young men of energy and constructive ability. Sir Arthur urged that only in some such way could the present machinery of civil government become competent to deal even with the task of preparation for war, for which in some ways the Civil Servant's experience is a definite handicap to him. The importance of bringing fresh blood and new methods of training into the administrative class of the Civil Service was also emphasized by Prof. Ernest Barker in an essay in the *Political Quarterly* so long ago as 1936 and afterwards reproduced in "The British Civil Servant" edited by Dr. W. A. Robson.

Failure to implement such criticisms or suggestions has in the meantime led to widespread concern as to whether the Civil Service, and with it the local government service, is capable of taking the measure of its war-time task. To exert our maximum effort, it is not sufficient to change Ministers and Under-Secretaries and to deal justly with causes of Parliamentary inefficiency. The increasing extent to which under modern conditions the permanent Civil Service has come to control the key-points in national administration makes it essential that we should consider carefully whether, by outlook, training and technique, this machinery is competent to discharge its duties at the tempo demanded by war-time conditions.

In such an examination there is, of course, no suggestion of departure from the high traditions of integrity, capacity and devotion to duty which have given the British Civil Service its world reputation. What has to be recognized is that the Civil Service attained its position of eminence in easier and more spacious days than our own, and that the fundamental principles of lengthy examination of all proposals and minute control of expenditure, on which its work is based, operated formerly in a restricted field. There is now real danger that loyalty to these principles, good and sound in themselves, may be carried to a point which delays action where speed is essential to safeguard our very existence.

It is now generally recognized that the growing complexity of the task of national administration, in peace no less than in war, makes demands on the machinery for which training in precedent is not the primary qualification. Parliamentary government indeed depends for its efficiency upon the existence of a body of permanent officials, serving all Governments alike and preserving the continuity of stabilizing traditions. Nonetheless, it is essential that this permanent service should be characterized not merely by vigilance, integrity and loyalty to tradition, but also by receptivity to new ideas and flexibility of mind Absence of such receptivity and flexibility, it is argued, are seriously affecting our war effort.

This position is attributed not merely to defects in training, among which the absence of a scientific outlook may well be noted. It is attributed also to the destruction of ability in the War of 1914–18, which robbed the Civil Service of many who would now have been its natural leaders. It is attributed also to the tendency of policy in the last eight years to sap the vigour and integrity of public life, checking initiative and independence in the Civil Service, thus fostering the worst features of bureaucracy.

If the immediate needs of the hour are to be served no less than those of reconstruction and re-integration after the War, some means must be found immediately of redressing this situation, whether by bringing in fresh blood or giving real opportunity to the younger men of first-class ability who are undoubtedly to be found in the Civil Service. Besides the introduction of ability from outside and the extension of transfers or promotion, devolution of authority at the lower levels to hasten decision is no less imperative than changes in personnel. There is no room for inertia or for the leisurely methods of an earlier period. We must be prepared when necessary to take drastic action to secure competence and prompt and efficient administration; only thus can we hope to see the immense resources of good will and effort stirred up by the challenge of recent weeks directed into the channels which will best serve the national purpose. From top to bottom of the administrative machine, there must be an energy and drive no less intense than that which has led so many to sacrifice leisure hours, possessions and life itself at the nation's call. Coupled with it there must be a sense of values and a width of outlook which will ensure the weighing of all factors and the basing of decisions on facts no less scientifically or surely ascertained because they are determined at the same pressure and strain which the whole nation now endures. Scientific workers may well hope that changes in the Civil Service imposed to meet our immediate War needs may facilitate the speed of a scientific outlook which will lead to much more effective use being made of our scientific resources to all departments of the national life.

TOWARDS THE NEW SYSTEMATICS

The New Systematics
Edited by Julian Huxley. Pp. viii+583. (Oxford: Clarendon Press; London: Oxford University Press, 1940.) 21*s.* net.

DR. HUXLEY and his co-authors have succeeded in producing a book which makes most stimulating reading. In all, twenty-two authors have contributed a chapter each and, as mentioned in the foreword, British authors predominate, since it was felt that this would facilitate the co-ordination of the articles. Where Great Britain could not supply a suitable authority on some subject, authors of other nationalities were invited to write a chapter. Some idea of the ground covered may be obtained from a few of the chapter headings taken at random: A museum zoologist's view of taxonomy; Mutations and geographical variation; Ecological aspects of plant taxonomy; Problems of the origin of species; Polymorphism and taxonomy; The statistical consequences of Mendelian heredity in relation to speciation; Taxonomic species and genetic systems; The new systematics of cultivated plants; and so forth. Minor systematics have naturally received the greatest share of attention for the very good reason that it is the minor units which most urgently require attention, and also, as it happens, they are the most amenable to experimental analysis.

If the reader expects to find concrete suggestions for a radical revision of the present taxonomic system he will be disappointed, for the book is mainly concerned with the discussion, in the light of recent experimental evidence, of the processes which are responsible for initiating and maintaining population differentiation. In fact it provides an admirable survey of the present-day problems which confront the systematist and his colleagues in other fields of biology.

A point of particular interest to all taxonomists which emerges from this general survey is that the available evidence amply justifies the majority of species being regarded as truly biological units separated from each other largely by genetical or chromosomal barriers to free interchange of genes. Nevertheless, in certain circumstances this isolation may be broken down and a complicated system created; such a case is illustrated in Chapter iv. At a lower taxonomic level the study of micro-evolutionary processes is of equal, if not of greater importance to the systematist, for unless the variational categories are given due consideration it can scarcely be hoped to put minor systematics on a satisfactory footing. The new mathematical interpretation of the consequences of selective processes operating under different conditions has obvious taxonomic implications, and in Chapter v it is shown that random differentiation is likely to be favoured when the breeding community is very small. Examples of differentiation probably due to this cause are given in Chapter ix.

Sometimes the formation of closed breeding communities may have rather unexpected results, results which may have little or no hereditary basis. For example, although structural differentiation is not involved, the chaffinches in the southern U.S.S.R. can be distinguished "solely on the basis of variation in song, into well-defined populations each confined to a given area" (Chapter xi). In Chapter iii, however, it is pointed out that territorial fragmentation of a population is not necessarily a sure guide to the degree of isolation actually afforded to its local colonies; this gives point to the value of careful field work in connexion with taxonomic investigations. Moreover, the methods of collecting suitable samples for taxonomic work deserve much more thought than hitherto: to give only one example, for a critical examination of polymorphic populations it may be necessary to collect a series of samples over a period of years for reasons mentioned in Chapter xix.

Some biologists will, no doubt, disagree with the view expressed in Chapter xv to the effect that for a classification to be natural it must necessarily be phylogenetic. It is fairly certain that any classification involving minor units is bound to include many populations of known biological significance, but the precise 'natural' affinities of which are simply a matter for conjecture. In contrast, a natural classification is defined in Chapter xvii as one "which groups together individuals having a large number of attributes in common, whereas an artificial classification is composed of groups having only a small number of common attributes . . . both types are created by the classifier for the purpose of making inductive generalizations regarding living things". One obvious advantage of an interpretation of a natural classification in this logical sense is that it does not carry with it the implication that classifications which are not 'natural' are merely keys for convenience and thus devoid of true biological meaning.

Under the present taxonomic system it is usually possible to refer an individual specimen in terms of morphology to its proper species. This means that the species represents both a discrete morphological class and, as mentioned previously, a true biological unit. But unfortunately, as many examples throughout the book show, this coincidence of the biological unit with the morphological class by no means invariably holds. Apart altogether from the fact that some differentiated biological units possess no distinctive morphological features, there are many other instances where minor populations can only be distinguished by their different average expressions of one or more quantitative characters, or by different proportions of contrasting qualitative characters. That is, discreteness in terms of morphological discontinuity is frequently lacking. But since characters of this kind are undoubtedly valuable as guides to the biological status of populations, although not being of primary classificatory value themselves, taxonomic emphasis in such cases must be shifted from the morphological class to the population's variational category as determined by a combination of morphological, ecological, genetical and cytological investigation.

The question therefore arises: Should units, so difficult to define with morphological precision, be incorporated in the existing taxonomic system? Essential as the delimitation of minor populations is for both theoretical and economic reasons, it would be most unfortunate, as is clearly indicated in Chapter xviii, if by widening the scope of traditional taxonomy its practical functions were to be diminished in the process. The alternative is to adopt a subsidiary classification with its own distinctive terminology. Many new taxonomic categories have been proposed within recent years (a few of which may yet find a place in some such subsidiary scheme), and it is perhaps a pity that their relative merits or demerits have not been critically discussed in the present volume.

J. W. GREGOR.

GROUP THEORY

The Classical Groups

Their Invariants and Representations. By Prof. Hermann Weyl. (Princeton Mathematical Series, 1.) Pp. xii+302. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1939.) 4 dollars.

Topological Groups

By Prof. L. Pontrjagin. Translated from the Russian by Emma Lehmer. (Princeton Mathematical Series, 2.) Pp. ix+299. (Princeton, N.J.; Princeton University Press; London: Oxford University Press, 1939.) 4 dollars.

IT is convenient to review these two books together since they are complementary to each other, with a negligible overlap, and there is an interesting contrast between their characteristic features. Between them they present some of the most interesting work which has been done on groups during the last twenty years, largely by the two authors themselves, and the Princeton University Press is to be congratulated on the first two books in its new series.

The groups which are indicated by the title of Weyl's book are the full group of linear transformations, $GL(n)$, the orthogonal group, $O(n)$, and the sympletic group, $Sp(n)$, in Cartesian n-space. The co-ordinates for the latter are taken from a given field, which is subject to certain conditions, but need not be the field of real or of complex numbers. The sympletic group is what has often been called the complex group, namely the subgroup of $GL(n)$ (n even), under which a non-degenerate, skew symmetric bilinear form is left invariant.

Using the idiom of some thirty years ago—for nowadays the theory of groups, and especially the algebraic part of the Lie theory, is often included in the term algebra—these groups are studied from the algebraic point of view, rather than that of group theory. That is to say, nearly everything in the book is subordinated to a description of their algebraic invariants and representations in tensor space, as apart from their pre-eminence among the simple Lie groups. Whereas the classical theory of algebraic invariants, of which Cayley and Hilbert were the alpha and omega, was almost entirely confined to invariants under $GL(n)$, Weyl emphasizes the fact that each group has its own invariant theory. This fact, as he points out, is particularly significant in the light of Klein's description of a geometry as the theory of a transformation group. The account of invariants centres around the problem of constructing, first a basis for the rational, integral invariants of one or more vectors, under a given group, and secondly a complete set of relations between these basic elements.

As a preliminary to the discussion of representations in tensor space there is an account of linear associative algebras, with special reference to simple algebras and the commutator algebra of a given algebra. This is divided into two parts. The first contains an account of representations, and Wedderburn's theorem that any simple algebra is equivalent to a complete matrix algebra, with elements in some division algebra. The second part explains the reciprocity between the invariant sub-spaces in the regular representations of the group ring, ρ, of a finite group, and the sub-spaces which are invariant under the commutator algebra of a given linear representation of ρ. This is applied to the representations of $GL(n)$ in tensor space by taking ρ to be the symmetric group in f things, and deriving the primitive idempotents from the Young symmetrizers.

Two chapters on the representations of $O(n)$ and $Sp(n)$ are followed by what is, perhaps, the kernel of the book, namely, the chapter on characters. The characters of a given representation of $GL(n)$, $Sp(n)$ or $O(n)$ are calculated with the help of the unitary group. Two methods are given. The first is transcendental in that it involves some simple topological and analytical considerations. The second is purely algebraic and depends on the relation between the representations of $GL(n)$ and of the symmetric groups. The Poincaré polynomials for the various groups considered are given at the end of the chapter. The book concludes with second chapters on invariants and on matric algebras.

Pontrjagin's book opens with three fairly elementary chapters, one on the generalities of group theory, one on topological spaces, and one on topological groups. These are followed by a chapter on the representations of an arbitrary compact group satisfying the second axiom of countability, which is based on the construction of an abstract invariant integral over the group. It is shown that the elements of the matrices which constitute the representations, selecting one from each class of mutually equivalent representations, form a complete set of functions on the group, meaning that a suitable linear combination of these, with constant coefficients of which all but a finite number are zero, provides an arbitrarily close approximation to a given continuous function of elements in the group. The characters of the representations constitute a complete set of class functions. The next chapter presents the theory of orthogonal, commutative groups, which was developed by Pontrjagin himself in connexion with Alexander's duality theorem. It also gives a brief account of topological fields, including the theorem that the real and complex fields, and the quaternions, are the only locally compact, connected topological fields which satisfy the second axiom of countability. This is followed by three short chapters on Lie groups, compact groups whose dimensionality is finite, and on locally isomorphic groups respectively. The second of these contains von Neumann's solution, for compact groups, of the famous problem, which was proposed by Hilbert, to prove that any 'locally Euclidean' topological group is a Lie group.

The book concludes with a fairly complete account of the foundations of the Lie theory. This does not include the deep algebraic analysis of an infinitesimal group, or Lie algebra as it is now called, which was originated by Killing and carried out by Cartan. But it goes beyond the elements of the subject in giving, among other things, the third fundamental theorem of Lie in its complete form. The proof given depends on E. E. Levi's theorem that any infinitesimal group consists of its maximum invariant solvable sub-group, together with a semi-simple sub-group.

It will be seen from this brief description how the two books complement each other. Weyl presents a very thorough and complete account of certain groups in an algebraic setting. Pontrjagin is interested in general classes of groups and his background is primarily topological. The characteristic theorems in Pontrjagin's book are of the kind whose discovery demands imaginative brilliance, and when discovered can be presented in such a way that they are easy to follow. Of course, this implies a high tribute to the exposition. Indeed, the lucidity with which this book is written amounts in itself to genius, and the translator also deserves high praise. To return to the theorems, they are easy to follow just because of their generality. By contrast, the main theorems in Weyl's book are more special and, at the same time, more explicit. They do not merely assert existence, but actually calculate whatever is in question (a class of invariants, characters, or what not), and are intrinsically more difficult than the type of theorem in which simplicity accompanies great generality. As Weyl says in his preface : ". . . I am convinced that the special problems, in all their complexity, constitute the stock and core of mathematics ; and to master their difficulties requires on the whole the harder labor."

J. H. C. WHITEHEAD.

SCIENTIFIC ADVANCEMENT

Science Front, 1939

By Dr. F. Sherwood Taylor. Pp. 301 + 8 plates. (London, New York, Toronto and Melbourne : Cassell and Co., Ltd., 1939.) 7*s*. 6*d*. net.

THE flood of literature which has recently been pouring into the scientific ocean with each passing day renders it more and more difficult for scientific workers to keep abreast of developments in science other than those in which they are particularly engaged. Usually, too, lack of time and facilities for visiting libraries make it especially inconvenient for non-specialist science advocates like members of the teaching profession to consult, even occasionally, current periodicals. Frequently, their only contact with progress in science is obtained through 'popular' works or standard text-books, and inevitably their teaching becomes antedated, and now that scientific research has acquired a momentum which is little short of bewildering, any means whereby current developments may be more quickly transmitted to other scientific workers, teachers, etc. (and hence to the community at large), should be carefully investigated. For this reason Dr. Sherwood Taylor's book is worthy of consideration. The author has selected a dozen topics which, to him, represent the most significant advances made in science in the years up to and including 1939. He has, of course, been unable to include references to the bulk of the original work of 1939, since much of it remains obscure, tentative and unconfirmed. The choice of subjects will not accord with all points of view as to what constitutes the more important developments in science—workers in the applied sciences would undoubtedly feel that they have been rather shabbily treated—but at least the author has revealed a sense of perspicacity.

In the chapter on plant growth there is a historical sketch of the discovery of the auxins and heterauxins and their use in commercial plant-growing processes. Brief reference is also made to recent developments in hydroponics. "Progress in Chemotherapy" is concerned with a description of the methods by which the sulphanilamide drugs, particularly Dagenan (*M. and B.* 693), were elaborated. The far-reaching importance of these drugs in treating bacterial infections, such as septicæmia, pneumonia, meningitis and gonorrhea is graphically presented. In this chapter the author occasionally departs from factual statements and introduces opinions which are highly controversial. It is extremely doubtful, for example, whether Dr. Taylor is justified in speaking for all members of enlightened communities when he writes ". . . there is no community which does not despise the (sexually) impotent with a contempt which the victim himself shares". It is to be hoped that there has been some change of outlook in the 270 years that have elapsed since Mr. Wycherley made a butt of a sexually impotent man in his play, "The Country Wife". A further matter for regret is that some grave moral and social issues are dismissed in a flippant manner.

In other chapters are discussed the steroid compounds and their physiological effects upon human beings, as well as recent investigations in protein chemistry and physics, including an account of the action of intracellular proteinases. "The War Against Cancer" consists mainly of a description of Kögl's method for investigating stereoisomeric proteins inside the cell. The insulin shock treatment for schizophrenia is adequately described, while in a further chapter is an account of the Bergius, Fischer-Tropsch and other processes for making oil from coal. The chapter on television is involved and confusing, and would offer considerable difficulty to non-specialists in this field. Among other topics discussed are the quartz clock, helium II, present-day atomic hypotheses, the aurora, and finally, an account is given of modern ideas in astronomical science, this being partly devoted to R. A. Lyttelton's binary star hypothesis of planet origin and partly to interpretations about the composition and distribution of bodies in space.

By his industry in collecting material, and his assiduousness in collating it, Dr. Sherwood Taylor has made a substantial contribution to extending the range of science. On its merits his book deserves a wide circle of readers.

T. H. HAWKINS.

MENTAL TESTS

The Measurement of Abilities

By Dr. Philip E. Vernon. Pp. xii + 308. (London: University of London Press, Ltd., 1940.) 10*s*. 6*d*. net.

IN the past five years or so, the work of the International Institute Examinations Enquiry in Great Britain and elsewhere has, to some extent, awakened the public to the need for some radical revision of the examination system. Those who are alive to this social need will welcome Dr. Vernon's book, for it provides for teachers, school medical officers and students of education generally an up-to-date survey of simple methods which can readily be applied to this end.

Under present evacuation conditions, the necessity for just and accurate methods of assessing the abilities and attainments of school-children is particularly urgent. Large numbers of children will have missed many months of their normal education or will have had their normal course of development hindered or diverted. The discrepancies between ability and achievement will probably become more irregularly distributed in the school population. The book under review gives the teacher, headmaster and school examining bodies a means of overcoming these difficulties.

About half of Dr. Vernon's book is devoted to elementary statistical techniques applicable in educational work. The author's aim is wholly practical, so considerations appropriate to statistical theory are omitted. A wealth of illustration is provided of almost every type of problem in evaluating ability or achievement that might arise in school or clinic. The remainder of the book is mainly a critical account of mental tests and examinations, especially of the new type. The sections on construction and improvements of new-type examinations are particularly useful.

The author admits that contemporary psychological and educational research, unfortunately, makes far too much use of correlational techniques, while neglecting such valuable methods as the analysis of variance. In spite of this, we find about fifty pages devoted to the former and a brief single page, conveying little, to the latter.

The statement (p. 161) that most ways of factorizing tests "will lead to quite illogical results" must be questioned. If different results are obtained from different methods of factorial analysis, this is because these methods have different objectives and consequently vary in procedure as, for example, in estimating the diagonal cells in a correlation table. The final results of different methods may not be comparable, but they can scarcely be called "illogical".

J. I. COHEN.

KITCHEN WASTE FOR FEEDING FARM STOCK

By JOHN BEHARRELL,
BRITISH FEEDING-MEALS AND MILK PRODUCTS CO., LTD.

NEEDS and risks of war have enforced a drastic reduction in Britain's imports of food for livestock, and because of this the Minister of Agriculture recently warned those farmers who have been mainly dependent on supplies of grain and meal that they must prepare to cut down the numbers of their pigs and poultry to one third by the autumn.

There were on farm holdings in Great Britain in June 1939, 3,750,000 pigs and 63,000,000 poultry—including turkeys, ducks and geese; and a more recent census, taken last spring, showed, according to an official statement, that these numbers had undergone scarcely any diminution. Their management and care represent a considerable industry, and a capital expenditure of far more than £10,000,000 for housing and equipment. Large-scale reductions of pig and poultry stocks would therefore cause considerable hardship and, at the same time, appreciably lessen the available supplies of eggs and bacon.

Search for possible substitutes for imported feeding stuffs has directed attention to edible kitchen scraps, which hitherto have been wasted by the local authorities. Estimates of the quantity of edible kitchen waste produced in Great Britain vary. Mr. Price, an official of the borough of East Ham, said recently that food wastage averages 1 lb. per family daily. On this basis, and representing a family as 4·5 persons, the yearly waste of edible material in Great Britain would exceed 1,500,000 tons. Another authority has placed the national food waste at the much smaller average of 1 ton per 4,000 persons weekly, or rather more than 600,000 tons a year for the whole population. If this conservative basis be accepted, London alone is producing annually more than 100,000 tons of edible waste.

Obviously the best way of utilizing domestic food scraps is to keep poultry or pigs, and the new Order in Council setting aside tenancy and other restrictions on 'back garden farming' will no doubt help in this direction. An active campaign is in progress to stimulate the formation of cottagers' and allotment holders' pig clubs, which will make it their business to collect the food waste. As an inducement to them, the Ministry of Food has promised to earmark a proportion of available feeding meals to supplement the scrap collection.

A few farmers utilize swill from neighbouring towns, but are under compulsion to boil it. Neglect to boil thoroughly or even at all is declared to have been responsible for numerous recent outbreaks of foot-and-mouth disease and swine fever.

There are urban councils and boroughs enterprising enough to sort out and sterilize edible waste and either sell it to farmers or use it in their own piggeries. Watford, between January 14 and June 8 last, saved 210 tons, and besides selling to nearby farmers, has been feeding as many as 260 pigs at a time. Employees of Tottenham Cleansing Department have been encouraged to keep their own pigs, and now a hundred animals are being fed mainly on house scraps.

But after these and similar praiseworthy efforts have been taken into account, and after full allowance is made for a big prospective increase of poultry and pigs in back gardens, there will still remain an enormous residue of waste.

A new Order by the Ministry of Supply compels the larger local authorities to rescue metal and paper from domestic refuse, and also requires householders to do their part in the salvage. Provisions of the Order may soon be extended to food waste. But while non-perishable substances can be saved and transported at convenient times to conversion factories, food must be handled promptly if decay is to be arrested.

Fortunately, a number of well-equipped factories exist in various parts of Great Britain for the utilization of waste from the fish markets; and, until a few months before the War, were producing more than 70,000 tons a year of white-fish meal. On the declaration of War, more than one half of the country's fishing fleet was occupied on patrol work and other defence duties. The ports of Hull and Grimsby were almost closed and the various white-fish meal factories from Aberdeen in the north to London in the south were laid idle because of the lack of raw material. All these factories can convert any perishable food material into a dry, sterile meal, and indeed they have the equipment to handle a very large proportion of all the country's food waste.

The London factory with which I am associated has been converting market and domestic waste into a feeding meal for the past ten months, and is capable of dealing with 50,000 tons annually. The factory has been placed at the disposal of the Ministry for the duration of the War without profit. Already a number of London municipalities are collecting the food scraps, which consist of vegetable leaves, potato peelings and other residues, portions of bread and cake, particles of meat and fat, and are delivering them to the factory daily. The City of Westminster has instructed its street sweepers to make a systematic collection of kitchen waste. Tottenham, one of the pioneer boroughs in the salvage of domestic waste, is collecting about 25 tons of food scraps weekly. East Ham started experimentally in April; during the week ending June 22, thirty-three of the Council's sweepers brought in 13 tons of edible waste from 15,000 houses, and it is hoped to increase this quantity very considerably.

In these and other London areas the scheme has started with distribution by the Women's Voluntary Services of literature which explains the urgent need of war-time economy, and asks housewives to place their food scraps in a separate container, such as a cardboard box or carrier bag, which can be emptied by the sweeper as often as he calls. They are also asked to exclude tea leaves, orange and similar skins and rhubarb leaves.

At the present moment the London factory has guaranteed a minimum payment of 25*s.* per ton delivered to the works, based upon the market price to the farmer; but all public authorities have been assured that if after three months an audit by the Ministry of Supply or other authority shows a higher price to have been justified, the difference will be placed to their credit, and the local authority, and indirectly the ratepayers who have provided the material, will receive the benefit.

In heavily rated boroughs the new source of revenue from reclaimed waste is welcomed. East Ham, last May, received more than £1,000 from salvage, and Tottenham's gross income from this source is at the rate of approximately £15,000 a year.

As soon as the food waste reaches the factory, it is taken by conveyors to drying cylinders in which it is sterilized at 250° F., and dried until it is reduced to one fourth of its original bulk; after drying, the material is ground to a fine meal. Analysis of a sample of this meal by Dr. Bernard Dyer and Partners Ltd., shows the following:

Moisture	7·25
Oil or fat	8·00
Crude albuminoids (protein)	20·95
Digestible carbohydrates	41·17
Indigestible fibre	7·20
Mineral matter	15·43
	100·00

The production starch equivalent is calculated at 63, the protein equivalent at 15·8, and the linseed cake equivalent at 85, entitling dried town-waste to rank among concentrated foods. The mineral content is noteworthy because it includes 3·4 per cent of lime and 1·65 per cent of phosphoric acid. These are in the satisfactory ratio of 3·4 of calcium to 1 of phosphorus, and would make unnecessary the addition of a mineral supplement to any ration of which the meal forms a part. One feature revealed by the analysis is the presence of 30 parts of carotene per million—about the same proportion as is found in meadow hay. As the precursor of the fat-soluble vitamin A, carotene can play an important part in the nutrition of animals or birds which do not receive cod liver oil or a liberal allowance of green food.

Actual farm tests have shown that any mixture containing the town-waste meal is eagerly eaten by pigs and poultry, and that the response in growth or egg production is all the more satisfactory because in recent months they have not received as large a proportion of protein in their ration as they need. Digestible protein and its equivalent are utilized by the living body to repair waste, build up flesh and perform other vital functions. They cannot be stored, and as any excess of requirement is eliminated a fresh supply must be constantly maintained. A ration is wasteful and unprofitable if it is deficient in protein or in those minerals which are closely linked with them in the processes of nutrition.

Imports of oil cakes and similar concentrated foodstuffs rich in protein have been among those greatly curtailed, and supplies that are available must be reserved mainly for the feeding of dairy cattle. Substances consisting principally of protein, such as white-fish meal, dried milk and dried blood, are also restricted, and it is accepted as sound policy by the Government that it will be fairest to the farming community as a whole if they are incorporated in compound meals and so shared out impartially. When combined with town waste, they make a meal so highly concentrated that it can be used in the proportion of 1 part to 8 of cereals, and will go far towards meeting the normal requirements of farm stock.

Accepting the estimate quoted above of an annual domestic wastage of at least 500,000 tons of food in Great Britain, there must be material available for the production of a minimum of 100,000 tons of a dry, sterile and wholesome foodstuff which agriculture urgently needs. At about £12 5*s.* per ton to the farmer, it would be bought as quickly as the factories could maintain production, and would then be converted by the kindly processes of Nature into most useful food for the nation.

Housewives have shown themselves eager to help as soon as the need has been explained to them, and wherever collection facilities have been organized. Only systematic effort on the part of public authorities is now needed to make a very great success of the campaign.

GEOLOGY AND EARLY MAN: II*

By T. T. Paterson,

University Museum of Archæology and Ethnology, Cambridge

A Classification of Lower Palæolithic Cultures

The Lower Palæolithic nomenclature is rapidly approaching a state of complete chaos. Industries are found in greater frequency and their discoverers with enthusiasm set up not only new industrial names but also cultural. Correlation and comparison is becoming more and more difficult. Convergent technical similarities are wildly seized upon as indication of cultural spreads. A flake with plain, high-angled striking platform denotes the presence of the Clactonian culture even though found thousands of miles away from the home of that culture (*sensu stricto*). It seems the time has come to attempt to put order into this muddle of names, and it has been found that the application of a binomial system is of great assistance. The following is concerned only with cultures appearing in the Pleistocene up to and including phase u_2 and not with the 'Middle Palaeolithic' of u_3 or the 'Upper Palaeolithic' of the end of the Pleistocene.

Two great families are recognized: the *Acheul* and the *Clacton*. The Acheul elements of culture comprise the *biface*, manufactured from a given mass of material by striking off flakes from upper and lower surfaces in such a manner that the edges separating these surfaces are defined working edges, a form being obtained which can be included under the group name biface; flakes produced during the manufacture of the biface; and controlled secondary working (which does not appear in the very early Acheulian industries). The Clacton elements of culture comprise a series of ten types of cores, with the corresponding flakes removed from them: the irregular mass, the asymmetrical, the simple pebble proto-biconical, the multiple pebble proto-biconical, the biconical, the asymmetrical biconical, the proto-tortoise, the convergent tortoise, the longitudinal tortoise and the steep core. There is also a series of artefacts made from pebbles, flat based—end, side, and boat-shaped; rounded—with pointed or convex edges; nucleates (commonly called 'choppers').

The Acheul family shows no subdivision into what might be called genera, but it is otherwise with the Clacton family.

Family	'Genus' (Culture)	'Species'
Clacton	Breckland	
	Levallois	
	Moustier	
	Soan	Kafuan-Oldowan pre Stellenbosch and Stellenbosch I Anyathian, etc.
	Choukoutien	

Combinations of the Clacton elements constitute the various forms of culture or genera. In Europe the Breckland (hitherto known as the Clactonian *sensu stricto*) is the precursor of Levallois and carries the same generalized core elements as the Soan, which varies only in the dominant presence of pebble tools. The Levallois is a culture which early (end of phase m_1) separates off from the Breckland. The Moustier does the same at a somewhat previous time. The Soan includes the Kafuan-Oldowan complex and the various pebble 'cultures' found in East Africa, the pre- and early Stellenbosch, and the Anyathian from Burma, besides the industries discovered by Collins in Malaya, and by Koenigswald in Java. The Choukoutien is very closely allied to the Soan, especially in the light of the bigger pebble elements it carries. The material, as in the Anyathian, plays a most important part.

Where cultures come into contact, which was a very common occurrence especially after periods of climatic severity—cold in the north and aridity in the south—hybridization took place. The resultant mixed culture is therefore named according to the group cultural elements involved. The dominant group is given the 'generic', substantival name, and the secondary the 'specific', adjectival. A prefix is added to indicate time relationships, and a suffix where necessary to show local variation. An actual case is the Upper Brecklandian Acheul (Hoxne), which is that variety of industry occurring during phase u_2 at Hoxne in which the dominant element is Acheul and the secondary Breckland. Or in East Africa, the industry of the M-Horizon would be called Middle Acheulian Soan (Oldowan), so signifying the dominant Soan (Oldowan) element and the age as phase m_2.

The accompanying three-dimensional diagram (Fig. 1) represents in the simplest fashion the culture development throughout the Pleistocene, all but the last phase u_3. In the Lower Pleistocene

*Continued from page 15.

there occurred the first great subdivision of cultures, probably from a very generalized ancestral pebble tool form. The evolution to the Acheul form is partly illustrated in *analogous* fashion in Stellenbosch I (which is, of course, much later and Soan). It should be stated here that according to the definition of Acheul culture elements given above, the Abbevillian can have no separate cultural significance, but represents only an early stage in the development of the Acheul culture. Lower Acheul, which occupies phase m_1, is here understood to include late Abbevillian. Early Abbevillian would then become the pre-Acheul of phase l_2 of the Lower Pleistocene. Corresponding pre-Clacton and pre-Soan occur in l_1. Lower Breckland and Lower Soan come in phase m_1 like

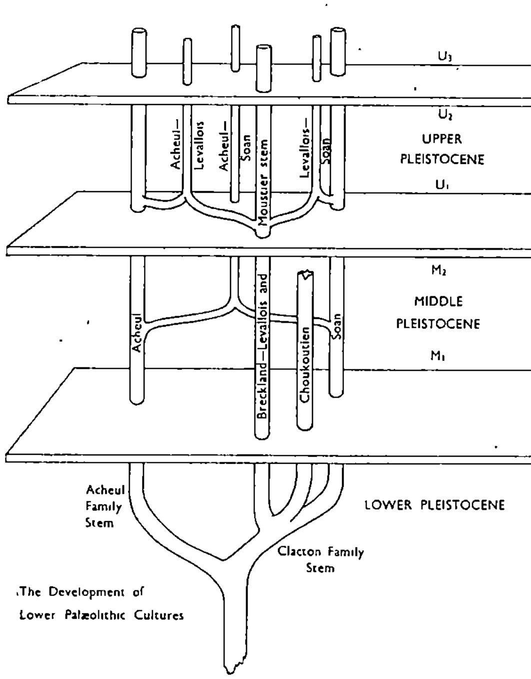

Fig. 1.

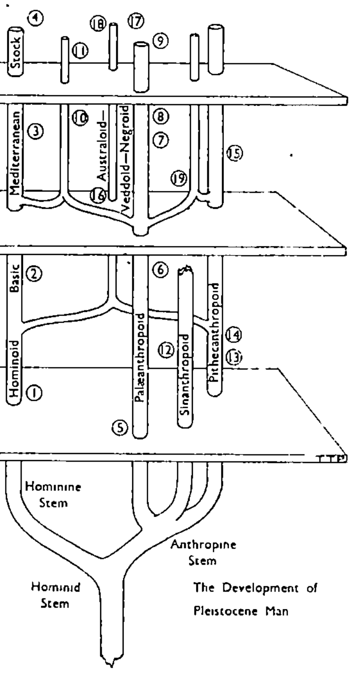

Fig. 2.

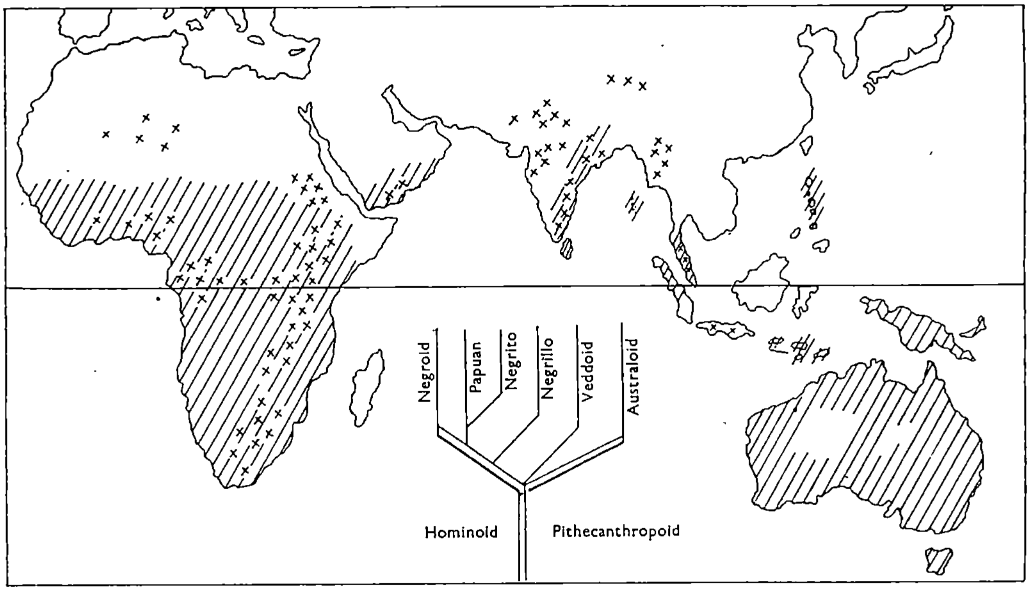

Fig. 3.

SHADING REPRESENTS THE DISTRIBUTION OF AUSTRALOID–VEDDOID–NEGROID STOCK ; CROSSES, THE SOAN CULTURE.

the Lower Acheul. The Middle Acheul, Breckland and Soan occupy m_2, Upper of all three in u_1 and u_2 and Final in u_3*. Lower, Middle, Upper and Final Levallois, and Moustier, occur in phases m_2, u_1, u_2 and u_3 respectively.

In the Middle Pleistocene in tropical latitudes the Soan and Acheul came together and we find in South Africa Stellenbosch II, in East Africa the Sangoan and the Middle Acheulian Soan (Oldowan), and in Peninsular India, Middle Soan Acheul and Middle Acheulian Soan. This hybrid culture form may develop on its own lines ; for example, as the Tumbian in East Africa, and a Tumbian-like culture all over India in the late Upper Pleistocene. The climatic extremes of the dry phase of m_2 in the tropics and the third glacial in the north brought all three main cultural groups together and much contact took place. In East Anglia, for example, there are Upper Brecklandian Acheul (Hoxne) and (Elveden), Upper Acheulian Levallois (Southacre)†, Upper Soan Levallois and Upper Levalloisian Soan in North India. Such hybrid forms developed on into phase u_3, when the great climatic extreme during the fourth glacial period not only wiped out Pleistocene faunas but caused again tremendous upheaval amongst mankind—the 'Middle Palaeolithic', essentially a stage of flux, came into being. Sometimes Levallois, sometimes Moustier, Acheul or Soan dominated, mixing and passing, coming and going—the pulsating birth of the 'Upper Palaeolithic' which emerged towards the end of the Pleistocene. In Fig. 1 no attempt is made to indicate the Middle Palæolithic flux, which would obscure the main form of the thesis the figure is intended to represent. Finally, it may be stated that within the Pleistocene, up to and including phase u_2, all industries can be adequately named by the use of one, or combinations of two or more, of six terms, Acheul, Breckland, Levallois, Moustier, Soan, Choukoutien, and with the aid of suffixes and prefixes, any special local characteristics (varietal forms) and the ages respectively can be represented.

THE DEVELOPMENT OF PLEISTOCENE MAN

It is already well established that Palæanthropoid man is associated with 'Levallois' culture and '*Homo sapiens*', as distinct from '*Palaeanthropus*', with the Acheul. At the symposium on the Middle Palæolithic during the British Association meeting at Cambridge in 1938, I further demonstrated the association of the Breckland with Ehringsdorf type, Levallois with Palestine type, and Moustier with the La Chapelle type. These associations are not given in the accompanying diagram (Fig. 2), since they would complicate the point at issue.

The first proposition submitted is that just as the cultural development shows mixture of cultural forms, so there have been produced hybrid physical forms owing to the mixture of stock following upon culture contact. Cultures do not remain consistently pure, nor do the racial stocks associated with them. Therefore in any attempt at classification of human Pleistocene fossils, regard must be paid to the factor of mixture, and even though a skull should show dominant characteristics of one racial form, nevertheless the presence of other racial characteristics must be indicated. It will be shown that racial hybridism was widely developed in the Upper Pleistocene, probably because of the same climatic catastrophe which altered the fauna, therefore the classification cannot follow the normal zoological method but the pedigree system applied to cross-bred domesticated animals. After all, man, especially in primitive societies, is essentially a domesticated animal subject to similar selective processes.

In the three-dimensional diagram (Fig. 2) two main lines represent the Palæanthropoid stem—associated with Breckland, Levallois-Moustierian—and a Hominoid basic Mediterranean stock—associated with Acheul. In the latter stem is placed Piltdown man (1) in very early Middle Pleistocene times. This interpretation of the age of the gravels of the Piltdown region, following Clement Reid, is based on their similarity to a very wide spread of gravels of m_1 age all along the southern coast of England. Swanscombe man (2) appears in phase m_2, in gravels heralding the third glacial stage. Here too, I suggest, would come the Kanjera skull. The artefacts associated with it are Middle Acheul on the system here adopted (Section C). From Upper Pleistocene loams of phase u_2 comes the Bury St. Edmunds fragment (3) and probably Galley Hill. At the end of the Pleistocene the man of Combe Capelle (4) represents this stock. In the Palæanthropoid stem there is *heidelbergensis* (5), probably intraglacial in age at the beginning of m_1. The age of the Steinheim skull (6) is doubtful, but it is probably similar to that of Swanscombe. Tabun and *ehringsdorfiensis* (7) and *neanderthalensis* (8) come from the Upper Pleistocene with *krapinensis* (9) at the end of the Pleistocene.

The contact between Acheul and Breckland—Levallois-Moustierian cultures first took place in phase u_1. In the Upper Pleistocene in a hybrid culture is found Skhūl man (10), showing not only Palæanthropoid characteristics but also others approaching those of the basic Mediterranean stock. At the end of the Pleistocene (11) come the

---

* A summary of the Acheul and Breckland subdivisions has already been given in NATURE, 143, 822 (1939).

† Discovered by Mr. J. S. Sainty.

La Chapelle group of types where the Neanderthaloid characteristics are still prominent.

It has been seen that there is a third great cultural stem, the Soan. So far the associated skeletal remains are Pithecanthropoid. Nevertheless the agreement of the distribution of the Soan culture with that of the Australoid-Veddoid-Negroid stock (Fig. 3) is suggestive. This brings forward the second proposition, that these peoples are survivors of those who produced the Soan industries. Towards the periphery of the distribution there is the series "*Homo*" *modjokertensis* (13) and *Pithecanthropus erectus* (14) in the Middle Pleistocene, *Homo soloensis* (15) in the Upper Pleistocene. Closely related is Pekin man (12) also of the Middle Pleistocene. In the latter period it has been noted that the Soan and Acheul cultures were in contact. In South Africa where this contact is extremely prominent has been found *rhodesiensis* (16), which is tentatively placed in phase u_1. The resemblances of this type to *soloensis* are quite well marked. *Africanthropus* (19) is associated with a contact Soan Levallois in the Upper Pleistocene. By this period the Negroid characteristics are already beginning to separate out; whereas, in the peripheral areas, a contact form has probably been evolving along its own lines, Wadjak (17), towards the modern Australoid. The Negroid characteristics of Grimaldi man (18) are well known. It is difficult to make any real constructive suggestion in relation to this 'outlier' except to point out that the Soan culture has reached well north in the Sahara, and the Languedocian of southern France may be its most northerly occurrence. The point must remain in question, but should the Soan have reached to Europe, then Grimaldi man must be the survivor of a contact between Hominoid and Pithecanthropoid types with probably late Palæanthropoid.

The third proposition is that the Australoid-Veddoid-Negroid stock differentiated in the following manner (see also diagram inset in Fig. 3). In Middle Pleistocene times somewhere to the west of Java, the Soan culture having already been widely distributed, a cross between a Hominoid and a Pithecanthropoid gave rise to the basal stock. On one side where the Hominoid element was stronger the Negroid developed, receiving very probably in the Upper Pleistocene some Palæanthropoid characteristics (vide *Africanthropus*). In the Australoid branch there was less Hominoid element. Early from the Negroid branch sprang the Veddoid, and later the Papuan racial type. The Australoid characteristics among some Negroid groups are due not to direct connexion with the Australoid race but are derived from a common ancestor, almost certainly Pithecanthropoid—as witness *wadjakensis*.

Thus it can be seen that, on general lines, morphological development corresponds with geological sequence. It must be remembered that should certain skeletal forms not agree with the theoretical morphological sequence, the lack of material is significant and survivals of early forms may occur out of their natural time grouping. In the Middle Pleistocene there was already a subdivision into three main stocks which it is suggested should be called Hominoid, Palæanthropoid and Pithecanthropoid (Sinanthropoid being regarded as close to the last). Since the assumption is made that hybridization occurred, then an absolute zoological taxonomic system ought not to be applied, but it is proposed that the skeletal remains belonging to these three generalized Middle Pleistocene stocks be given the status of genera. By the Upper Pleistocene, when much crossing had taken place, the various racial forms of present mankind were beginning to be moulded out. Remains from this period could then be given specific status. All later forms would be varieties of *Homo sapiens*. The suggested classification is set out below*.

LATEST AND POST-PLEISTOCENE. *Homo sapiens*, VARIETIES.

Homo species Upper Pleistocene	Homo *edmundi.* (Bury St. Edmunds) *londiniensis.* (Galley Hill), etc.	Homo *krapinensis.* *palestinensis.* *ehringsdorfiensis.* *neanderthalensis*, etc.	Homo *wadjakensis.* *soloensis.* *rhodesiensis.* *njarasensis.*
	(To be set up on a pedigree system.)		
Hominid genera Middle Pleistocene	Homo *H. marstoni.* (Swanscombe) *H. dawsoni.* (Piltdown) *H. leakeyi.* (Kanjera)	Palæanthropus *P. steinheim* (?) *P. heidelbergensis.*	Pithecanthropus *P. modjokertensis.* *P. erectus.* *P. pekinensis.*
Hominid sub-families Lower Pleistocene	Homininæ	Anthropinæ.	

It seems that of the three genera the Hominoid was predominant, the other two recessive, since it is the Hominoid which has alone survived in essence. The spread of the Hominoid stock which established its world-wide supremacy took place in the Upper Pleistocene and is associated with the distribution of the 'neanthropic culture'. Nevertheless, there seems to be no doubt that already before that the modern distribution was shaping itself. Weidenreich believes, for example, that he can see in *P. pekinensis* relationships to some present-day Mongoloids.

I would be grateful for criticism of these propositions.

* Mr. J. C. Trevor has been most helpful in discussing this matter.

THE SURVIVING CROSSOPTERYGIAN FISH, LATIMERIA

BY SIR ARTHUR SMITH WOODWARD, F.R.S.

IN NATURE of May 6, 1939, p. 455, Prof. J. L. B. Smith, of Rhodes University College, Grahamstown, announced the discovery in South African seas of a living Crossopterygian or paddle-finned fish. He recognized that it belonged to the group of Coelacanths, which was known only by fossils and was supposed to have been extinct since the end of the Cretaceous period. In the *Transactions of the Royal Society of South Africa,* he now describes in detail the remains of this fish*. Unfortunately, there are no more than dried remains; for when the specimen was sent to the East London Museum its scientific value was not appreciated, and it was entrusted to a taxidermist, who preserved little beyond the external parts and damaged some of these by piercing them with pins and nails. Prof. Smith laments his "relatively crude equipment" for dealing with the fish, but he is to be congratulated on his laborious effort and on the technical account of so much as he has been able to observe. His memoir is illustrated by an exhaustive series of photographs and a few diagrammatic text-figures. There is also an explanatory list of the numerals and letters used in all the illustrations, and this is arranged on a page which unfolds outwards so that it may be kept always in view.

The Coelacanths have changed very little since their first known appearance in Upper Devonian formations, and it is difficult to separate the new living fish from some of the old genera which are represented by fossils. For convenient reference, however, Prof. Smith has done well to give this fish a new generic name, Latimeria, which commemorates Miss Courtenay Latimer, the curator of the East London Museum. Very curiously, it retains the complete supplementary tail fin which characterizes the Jurassic and earlier genera, and thus differs from the latest or Cretaceous genera, Macropoma and Mawsonia, which have the tail extension reduced and lacking fin rays. Only the anterior dorsal fin, with its eight strong rays armed with upwardly pointing denticles, and the scales with their sharp denticles, are specially like those of Macropoma. The caudal fin seems to have a few more rays than any of the known extinct genera.

As in all Coelacanths, there are no scales on the head, and the sensory canals are conspicuous. The circumorbital plates, so commonly observed in Coelacanths, are absent. The two nostrils are well seen on each side of the snout, but Prof. Smith has been able to dissect this region and he thinks that they do not communicate direct with the olfactory capsules. These capsules are described as situated on either side of a large median chamber, which he names "ethmoidal nasal cavity"; and the cavity is said to be connected by tubes both with the two pairs of external nostrils and with a pair of openings on the front end of the snout. The remarkable arrangement needs further study in a better preserved specimen. The cranium, indeed, is so much damaged that Prof. Smith has been able to observe very little of it.

There is nothing unusual in the external bones of the head, but, as already suspected, it is now clear that the preoperculum is extended on the cheek as in the early Chondrosteans. There are also degenerate remnants of the suboperculum and interoperculum. The mouth is very interesting because, although there is no bony maxilla, this element is represented by "a thickened fold of skin" which bears the usual little tooth-plates or clusters of conical teeth. Especially important and new is the identification of the hyomandibular bone, which is described as "very firmly bound to the inner face of the anterior margin of the opercular". It is ossified only in its middle portion, the long ends remaining cartilaginous. From the hyomandibular there extends downwards and forwards a relatively large symplectic bone, which articulates with a hollow facet on the articular bone of the lower jaw, well behind the quadrate articulation. As Prof. Smith remarks, the arrangement is suggestive of that in the existing Chondrosteans. He points out that the facet on the articular bone has already been shown in published drawings of the lower jaw of the Devonian coelacanth Diplocercides; and he might have added that a pit in the same position has been described in the lower jaw of the Cretaceous Macropoma and Mawsonia.

The spiracle is supposed to have been functionless, but this portion of the head is badly preserved. The gill arches were destroyed, but the copula seems to show that there were only four pairs. Five pairs have been seen in some of the extinct Coelacanths.

The internal parts of the dried body have been so completely removed that little remains even of the skeleton. One hæmal spine in the tail, however, is seen to consist chiefly of cartilage surrounded by a thin cylinder of bone, thus exhibiting the structure to which the name Coelacanth (hollow spine) refers, for the cartilage disappears and leaves a hollow space in the fossils.

---

* J. L. B. Smith, "A Living Coelacanthid Fish from South Africa", *Trans. Roy. Soc. S. Africa*, 28, Pt. 1, 1–106, pls. i–xliv, 1939 (received April 1940).

The only new character described in the fins is the extension backwards of the membrane of the anterior dorsal fin beyond its eight rays. The extension is low and rapidly tapers behind, without any skeletal stiffening. The scales appear normal, and Prof. Smith observes ring-markings which he thinks prove the age of the fish to be between twenty and twenty-five years.

The exceptionally oily nature of Latimeria, already mentioned in the preliminary notice, is interesting geologically, because it indicates one possible source of the oil in many stratified rocks. Like most of the extinct Coelacanths, there is no doubt that it is a sea fish, not a straggler from a river. As Prof. Smith remarks, however, the annulation of the scales shows that it cannot be a denizen of the ocean depths. It must be well within reach of the ordinary fishermen, and the interest now aroused should induce the trawlers off the east coast of South Africa to save any more specimens which they may find.

OBITUARIES

Sir James Baillie, O.B.E.

SIR JAMES BLACK BAILLIE, who died on June 9 at the age of sixty-seven, was vice-chancellor of the University of Leeds from 1924 until 1938. A Scotsman, he was educated at the Universities of Edinburgh, Cambridge, Halle, Strasbourg, and Paris. At Edinburgh he had a particularly distinguished record, gaining the Ferguson scholarship and Shaw fellowship in philosophy, both open to graduates of the four Scottish universities. After graduation he was an assistant at the University of St. Andrews. Later he was lecturer in philosophy at University College, Dundee. He was professor of moral philosophy at the University of Aberdeen during 1902–24. He was knighted in 1931.

The most significant period of Baillie's life was when he was vice-chancellor at Leeds. He was keenly interested in problems of administration, and at Leeds this interest was fully satisfied. The University of Leeds saw great developments under his leadership. In 1925 an appeal was made by the University for the sum of half a million pounds for the purpose of erecting more adequate buildings. This appeal had realized about £700,000 at the time of his retirement, and many fine buildings had been erected, notably the Brotherton Library. Five new chairs and many lectureships and scholarships were instituted during Baillie's period of office, and valuable benefactions received. But human life is not merely thought or intellect in a narrow sense, as he himself showed in his "Studies in Human Nature"; there are other highly important activities. So Baillie did not forget, for example, the athletic and social sides of university life. Playing fields were developed at a cost of more than £50,000 and a beginning was also made with a new Students' Union, which has recently been completed.

In his administrative work Baillie showed great tenacity of purpose. He had the mind of an arbitrator, and indeed, both during the War of 1914–18 and since, he served in the capacity of arbitrator on several important Government commissions. His attitude of mind and methods were perhaps sometimes rather cold and impersonal. He had weighed the pros and cons, he had come to a conclusion, he must give effect to the conclusion for the conclusion's sake. But there was a warm and sympathetic side to Baillie's nature. He was an excellent host to a wide circle of friends and he was a good conversationalist and a good listener.

Baillie's main philosophical interest was Hegelianism. In 1901 he published a commentary, "The Origin and Significance of Hegel's Logic". His "Outline of the Idealistic Construction of Experience", 1906, is avowedly based on Hegel's "Phänomenologie des Geistes". Perhaps Baillie's most important contribution to philosophy was his translation, with an introduction and notes, of the "Phänomenologie". It appeared in 1910 and in a second edition, with a much improved text, in 1931. Its first appearance was particularly notable, for here was a major work of Hegel's made available in English for the first time. In 1924 Baillie was a contributor to the first series of "Contemporary British Philosophy", a collection of personal statements by leading philosophers, edited by J. H. Muirhead. He was also a contributor to Hastings' "Encyclopædia of Religion and Ethics", the *Hibbert Journal*, *Mind*, and other periodicals. As a philosopher Baillie was an ingenious and acute dialectician. He was, too, a most stimulating lecturer, illuminating his theme from all sides of human nature. In many respects his outlook was not unlike that of his illustrious predecessor, Thomas Reid, expounder of common sense. W. M. DICKIE.

Prof. Giuseppe Sanarelli

PROF. GIUSEPPE SANARELLI, the eminent Italian hygienist, whose death occurred recently, was born on September 24, 1865, at Monte San Savino, Arexzo. He studied medicine at Siena, Pavia, under Golgi, Munich under Pettenkofer, and Paris under Pasteur, and qualified in 1889 at Siena, where he began his career by being assistant to the professor of general pathology. In 1894 he was appointed professor of hygiene and director of the Institute of Hygiene at Siena, and during the next few years held corresponding posts at Montevideo (1895–98), Bologna (1898–1915) and finally at Rome.

Sanarelli's most important work was connected with the pathogenesis of cholera, typhoid fever, and spirochætosis, immunity and ultra-viruses. His name has been attached to the organism which is the cause of myxoma in the rabbit (*Sanarellia cuniculi*), but the organism which he called *Bacillus icteroides* and claimed to be the cause of yellow fever was shown by Reed and Carroll to be merely a variety of the swine cholera bacillus. In addition to numerous articles in periodical literature, such as the *Centralblatt für Bakteriologie*, *Comptes rendus de l'Académie des Sciences*, *Annales de l'Institut Pasteur*, etc., he was the author of several books. He was also the editor of the *Rivista di Malariologia*, which was founded in 1922 under the name of *Bolletino Malariologico*. He was the recipient of many honours. He was made a senator of Italy in 1920, and was rector of the University of Rome in 1922–23. He was also an honorary member of many learned societies in Italy and other countries. J. D. ROLLESTON.

Mr. F. M. Davis

EDUCATED at Harrow and at Caius College, Cambridge, Mr. F. M. Davis joined the staff of the Fisheries Department of the Ministry of Agriculture and Fisheries as an assistant naturalist in 1911; at the time of his death at the age of fifty-one he was principal naturalist in charge of the Fisheries Laboratory, Lowestoft.

Davis served in the War of 1914–18 as a captain in the London Regiment, was wounded, and held prisoner for nearly two years. On his return he spent many months carrying out investigations on trawlers, and he also made a very thorough survey of the fishing gear and methods employed in the maritime fisheries of England and Wales, the results of which are embodied in his well-known paper on the subject, now in its third edition (*Fishery Investigations*, Series II, 15, No. 2; 1936). He took part in an exploratory voyage to Lousy and George Bligh Banks in 1920. His subsequent work included several years investigation of the bottom fauna of the North Sea by means of the Petersen grab, resulting in two papers of great ecological interest, demonstrating *inter alia* the existence of vast beds of shellfish (Spisula and Mactra) on the Dogger Bank, which were subject to great fluctuations from year to year.

Thereafter Davis devoted several years to the practical study of the relation between the mesh of the trawl and the size of fish caught, and his results were basic for the international convention on mesh and size-limits signed in 1937. In the last year or two he became greatly interested in the great cod fisheries in the far north, and made several trips on trawlers to the Bear Island and Spitsbergen grounds. His bent was essentially practical; he was happiest at sea, and the vast experience there gained made him an acknowledged expert on all practical fishery problems, especially those relating to fishing gear.

Davis was a first-class rifle shot and had many successes at the Bisley meeting, which he attended regularly. His modesty was excessive; only those who knew him well could appreciate the shrewdness of his judgment and the depth of his knowledge, which he was apt to hide under a casual manner. He was greatly loved by his colleagues and a wide circle of friends. E. S. RUSSELL.

Mr. Jonathan Hodgkinson

OXFORD mathematics have suffered three grievous losses in the past few weeks by the deaths of Prof. A. E. H. Love, Mr. Jonathan Hodgkinson and Dr. E. G. C. Poole.

Jonathan Hodgkinson went up to Jesus College from Carlisle Grammar School as mathematical scholar in 1904. He won the University Mathematical Exhibition in 1906, was the Senior Mathematical Scholar in 1910 and obtained two first classes in the school of mathematics. From 1913 until 1921 he was a prize fellow of Merton College, one of the few colleges which retains this traditional reward of learning. During the War of 1914–18 he served in the infantry and with the Tank Corps as a major.

After the War, Hodgkinson became fellow and tutor in mathematics at Jesus College, and was for a time University lecturer in mathematics. He was a great teacher. He got good material with which to work and he made the very best of it. He worked his men hard but they responded, and the record of University honours in mathematics by the Jesus College men of the past twenty years is an impressive one. Although Hodgkinson was primarily a teacher he found time to do original work on the pure mathematics of applied mathematics. He was an authority on hypergeometric functions and published many papers on this and other subjects. For some years he was one of the three editors of the *Quarterly Journal of Mathematics*, and worked well and ungrudgingly at that difficult task.

In his college Hodgkinson was particularly helpful in matters of finance, where his analytical mind and shrewd commonsense were of value to his colleagues. Like so many of the mathematical and scientific dons in Oxford, he was an efficient administrator, and for some years wisely guided his college in disciplinary matters. During the last eighteen months his health had failed him, and though there were periods when it seemed that he might recover, at least in part, his health, he died on June 21. He was fifty-four years of age.

WE regret to announce the following deaths:

Mr. G. S. Blake, formerly geological adviser to the Palestine Government.

Dr. Alvin S. Wheeler, emeritus professor of organic chemistry in the University of North Carolina, on May 12, aged seventy-three.

NEWS AND VIEWS

Medicinal Plant Cultivation

EVENTS associated with recent developments of the War come as a disagreeable reminder of our dependence upon countries abroad for practically all kinds of vegetable materia medica. When Germany and areas in mid-Europe under German influence, followed by Poland, ceased to be sources of supply, the deficiency of most of the vegetable drugs could still be made good by imports from other countries. Belgium, Holland, France and Italy were alternative reservoirs which could be drawn upon abundantly, while the produce of areas in the Mediterranean zone, rich in many varieties of the raw materials of medicines, reached British ports almost unfailingly. Some of these outlets are now shut completely, and the rest of them have ceased to be easy of access. It is true that lands farther afield—India, various British Dominions and Colonies, the Americas, Japan, China and the Netherlands Indies, for example—can send us their produce, but most of these countries are almost as dependent as ourselves upon importation from the same sources as those from which we have obtained our supplies. This is all the more curious, because it would be difficult to name a single vegetable drug which could not be produced economically in some part of Britain overseas or in the Americas.

The need of the moment is to establish as speedily as possible a system by which Great Britain may provide itself with all the medicinal plants which can possibly be cultivated on British soil. Good stocks of the more essential of the vegetable drugs are already in the country, and if plans for extensive cultivation are brought into operation without delay, there need be no shortage of many of the commonly prescribed vegetable drugs. The Pharmaceutical Society is anxious to do what it can to support a campaign to make Great Britain as self-sufficient as possible in this respect; further, Mr. T. E. Wallis, Hanbury medallist for 1940 of the Society, has volunteered to give advice to amateur gardeners who are prepared to undertake the work of cultivation. Admittedly there is a limit to the variety of plants which can be grown in British soil, but home production can be supplemented by the support of Britain overseas. In past times when medicinal herb cultivation by smallholders has been attempted, an obstacle to complete success has been the absence of drying and collecting centres, but the need for production is now so urgent that it is impossible to believe that means will not be found for the proper organization of a necessary industry, even if the State has to lend a hand.

Work of the Patent Office

THE fifty-seventh report of the Comptroller-General of Patents, Designs and Trade Marks, for the year 1939, indicates that the steady increase in the number of applications for patents and complete specifications characterizing the previous three years continued until the outbreak of war, afterwards decreasing by about one third in comparison with the same period of the previous year (Pp. 26. London: H.M. Stationery Office, 1940. 6*d*. net). In regard to patents, the total number of applications was 33,109, of provisional specifications 20,095, of complete specifications 20,610, and of patents sealed 17,605, as compared with 37,973, 22,696, 23,098, and 19,314 in 1938, respectively.

The trend of invention showed considerable activity in the production of motor fuels of high anti-knock value by alkylating isoparaffins with olefines in presence of a catalyst. The preparation of organo-metallic compounds for addition to motor fuels to increase their anti-knock value has also received attention, as well as the synthesis of the hormones of the adrenal cortex. Marked progress has been made in the synthesis of some of the more important vitamins the chemical structure of which has recently been elucidated. Attention is being directed to methods of extracting cellulose from plant materials hitherto not utilized, such as highly resinous woods and certain grasses, and also to the preparation of polyamide resins for use in the manufacture of artificial fibres. The contemplated extension of full automatic working to the setting up of long-distance telephone connexions has led to considerable activity, and numerous aspects of passive defence such as respirators, air-raid shelters, electric torches, masks and shades, blinds and shutters, etc., also figure prominently.

Applications for licences under separate patents under the Emergency Act have numbered 754, and for the variation of pre-War licences in respect of individual patents 109. Orders have been made granting 207 licences in respect of separate patents and amending 12 pre-War patent licences. In dealing with applications for licences under this Act, it has been taken that the main object of the licensing provisions is to enable and encourage the working in Great Britain of useful inventions which are covered by enemy-owned patents, and for that reason could not or would not be utilized here during the War. Steps have also been taken to prevent the risk of publication abroad of details of any invention of which disclosure might be contrary to the interests of the realm or of service to the enemy.

Re-grassing

ADVICE supplied by the Welsh Plant Breeding Station at Aberystwyth on grassland management is sure to be studied with interest as it is based on so much practical experience. In its War Food Production Advisory Bulletin No. 1, entitled "Re-grassing" (1*s*.), Sir George Stapledon stresses the importance of developing a far-seeing policy, which both aims at increasing current food production and at the same time has due regard to creating enhanced fertility of the land for the future. Grassland now being ploughed up for cereal growing should be brought under some fertility sustaining rotation, while grassland at present too poor to be worth ploughing up for cereals should be improved as such, so that it can be ready for the plough in two or three years time. Further, every effort must be made to improve the quantity and quality of existing grass to compensate for the acreage lost to the plough.

The means of achieving these aims, Sir George maintains, is the ley, those of three years and upward making for a sound system of alternate husbandry, and the bulletin is largely devoted to describing methods which will most rapidly convert poor permanent grassland into good leys. Three main methods of procedure are given, namely, the sowing of seeds mixtures, with or without a cereal covering crop, directly on the prepared surface of the upturned sod, and the sowing of rape and Italian rye grass as a preparation for a subsequent ley mixture. The all-prevailing notion that a ley can only be economically established under a cereal nurse crop at the end of a rotation is shown to be contrary to facts, for experience has proved that newly broken grass is an excellent starting point and that a cover crop is not essential. The value of sowing pioneer crops such as Italian rye and rape on land which is at present unproductive is also strongly stressed, as it provides back end and early spring keep and will help to make the land sward- or cereal-worthy at a later date. The bulletin supplies numerous details regarding manuring and seeds mixtures and gives examples of the experience of farmers from different parts of the country in support of the policy advocated.

Family Allowances

IN a pamphlet entitled "An Aylesbury Broadside" (price 3*d*.), the *Lancet* surveys the case for family allowances. The subject is dealt with mainly as a public health problem, for in 1938 there were at least 189,000 school-children in England and Wales suffering from malnutrition. Unfortunately, in most cases wages do not expand with the advent of children, and what sufficed for the family of one or two children becomes inadequate when there are three or more. Further, malnutrition in men is serious enough, but it is trivial in its effects on the race compared with ill-health in child-bearing women. Food requirements and the cost of adequate diets are discussed, and from the medical point of view the *Lancet* considers that there is an excellent case for paying a flat rate of 5*s*. for every child in the country. The principle of family allowances is actually admitted in the case of certain income-tax payers and in separation allowances for the families of soldiers, and a growing number of industrial firms have established family allowance schemes of their own. Various suggested schemes are outlined, namely, to place the whole onus on the employer, to let the State pay out of taxation, or a contributory scheme in which employers, workers and the State all take a share. A State scheme would probably cost £118,000,000. Certainly a case seems to be made out for the payment of family allowances of the order of 5*s*. for at least the third and subsequent children.

Economics of the State

A PAMPHLET, "The New Social Order: its Mechanism", by a group of scientific workers, which is edited by A. H. Mackmurdo, emphasizes the importance of the economic position and advocates the elaboration of an economic unit to organize distribution of resources upon an equitable scale (London: The C. W. Daniel Co. 6*d*.). In each State, the national economy would be based on a fixed price for the staple foodstuff, this fixing the price of all home-grown foods and, in turn, the price of all national goods and services, and each living wage would be measured upon this price-scale. The social mechanism to remove the paradox of potential plenty and actual poverty is regarded as involving three changes: a radical change in the mechanism of a commonwealth distribution; an instrument for measuring the distribution of the portions of this common wealth to be distributed to the members of the community as co-partners of it; and a regulative organ to control and guide the highly specialized organs of production, regulate the machinery of distribution and control all national imports and exports. The first change involves a new wage system and the disappearance of public or private ownership in the fruit of the common effort. The second involves the establishment of a new form of national money, and in the third, growth of the social service conception is essential, leading to the development of occupational organizations, which will regulate the economic affairs of the industry or occupation in the interest of the whole community.

The School of Salerno

IN a paper read before the Section of the History of Medicine of the Royal Society of Medicine on June 25, Dr. H. P. Bayon referred to his previous communication on this subject (NATURE, March 30, 1940, p. 507), and said that it was generally agreed that a broad stream of Hippocratic medicine could be traced from classical times to the present day. Hippocrates was mainly concerned with the observation of symptoms for prognostic purposes, while Galen seven centuries later made diagnosis subservient to treatment. During the following nine centuries the Hippocratic stream became a mere trickle, just recognizable in the writings of philosophers like Hrabanus. In the ninth century the practitioner of medicine, when not a monk, was a *medicus* who employed spells and charms and could scarcely read or write. In the East, on the other hand, physicians and surgeons were trained by learned teachers. At the time of the first Crusade the Masters of Salerno first arose, adopted the title of *Magister* like that of expounders of the law and taught by means of the excerpts and compilations of Moslem and Hebrew writers like Constantinus Africanus, who died about 1087.

The Salernitans established by example and precept that the practitioner of medicine should be a learned person, not only a skilled craftsman. They concentrated on the treatment of symptoms, made a timid attempt to learn anatomy, and, what is particularly remarkable for their time and locality, avoided magical formulæ or miraculous faith-cures. It may be surmised that they modelled themselves on the practice of Moslem and Hebrew physicians. Their literary activity stopped with the sack of Salerno in 1196; but the famous edict of Frederick II regulating the practice of medicine was issued in 1240 when a "College" had been formed. The *Regimen Salernitatum* in its original form was not particularly important medically; when it became popular, it was altered by others; the significant Salernitan writings were *Copho, Antidotarium, Trotula* and *Rolandina.* The essential achievement of the Salernitans was the advancement of medical practice on those professional lines which it had preserved to the present day.

Stone Age Cilicia

A REMARKABLE prospect of the future which will lie open to intensive archæological investigation in Cilicia was given by Mr. Miles C. Burkitt in a report recently presented (May 7) to the Royal Anthropological Institute on his examination of the stone industries of the lower levels found at Tell Halaf, near Mersin. This Tell, which is being explored by the Neilson Expedition under Prof. J. G. Garstang (see NATURE, 143, 464; 1939), has proved to be one of the most important sites in the Near East. Mr. Burkitt's examination of the lower levels by a terrace excavation beginning at the lower limit of the Tell Halaf culture, and extending downward nearly to river-level, has revealed a proto-chalcolithic culture with deposits of 3 metres depth, and below this an upper and lower neolithic of 9 metres together.

Each of these deposits has yielded a characteristic pottery, of which the chalcolithic is a painted ware, some reminiscent of Nineveh, while other sherds resemble painted pottery of Thessaly. In this level mud-brick was in use and there was a poor industry of obsidian and chert. In the Upper Neolithic level the pottery was fine but undecorated. Mud-brick was not in use, while obsidian implements were more numerous than in the higher level. The pottery of the Lower Neolithic consists of hole-mouthed vessels of softer, coarser ware, which are well burnished and frequently show an incised decoration. Similar wares at present have been found only at Ras Shamra in the lowest levels. The obsidian industry is striking and includes beautiful lance-heads and daggers, flaked by pressure. These industries antedate anything hitherto discovered in this part of the Near East. In Mr. Burkitt's opinion these discoveries auger well for the prospects of the discovery of late Paleolithic industries in the many rock shelters to be explored in the foothills of Taurus bordering Cilicia.

Wolf-Children

IN his presidential address on this subject delivered before the Folk-Lore Society on February 21 (*Folk-Lore*, 51, 9; 1940), Dr. J. H. Hutton deals with the cases recorded from classical antiquity down to the present time of children having been reared by animals, especially wolves. The earliest record of a wolf-child which he has discovered in northern Europe is that reported by William Dilich in 1341 as occurring in Hesse. Two Lithuanian cases of wolf-children were described by Connor in his "History of Poland", published in 1698, since when no cases have been described in Europe. Many recent cases, however, have been reported from India, mostly from the United Provinces, and also from Central India, as well as from Africa.

Wolves are not the only animals which have been said to have carried off and suckled children. In classical antiquity, Atalanta is stated to have been suckled by a bear and Cyrus by a bitch, while in recent times bear-children, jaguar- and leopard-children have been recorded in India, and lion-children and a baboon-child in Africa. It is a remarkable fact that no stories of the kind have been reported from the New World, where examples of wolf- and bear-children might have been expected from North America and jaguar- and puma-children from South America. Although it has been suggested that wolf-children are idiots who have wandered into the jungle and taken up their abode in the dens of wolves, this hypothesis is by no means universally applicable, notably in the case of the jaguar-child in the North Cachar Hills, India. Dr. Hutton comes to the conclusion that the evidence from India of wolf- and leopard-children and from Africa of a baboon-child seems to support the hypothesis that the belief is founded on observed facts.

Research at Port Erin

THE report for 1939 (No. 52) of the Marine Biological Station at Port Erin, Isle of Man, drawn up by the director, Prof. J. H. Orton, shows that the oyster investigations and other researches have been continued and that the director submitted to the Manx Government a memorandum on the prospect of the development of an oyster fishery in the neighbourhood of the Isle of Man. It is stated that during the past year pressure of work caused Dr. R. J. Daniel to resign his directorship. Arrangements are being made for the transfer of the direction of the Station from the Department of Oceanography to the Department of Zoology in the University of Liverpool.

The new plans for the development of the Station unfortunately have all been temporarily cancelled owing to the War. These include increase of staff, new tanks, more efficient pumps, electricity for light and power, a store hut on the quay for gear, and funds acquired to keep the motor-boat continuously in commission and available for all research workers. It is to be hoped that these additions are merely postponed and that a successful future will be assured for this laboratory which has produced so much good work.

Swiss Short-Wave Emissions

AN article by Paul Borsinger, chief of the Swiss short-wave service, is published in *Swiss Industry and Trade* of May. The Swiss short-wave service was inaugurated some years ago. It was organized before the existence of an exclusively Swiss transmission station. The League of Nation's transmitter, located at Prangin near Geneva, was rented for that purpose at certain free hours. In the first stage, the service was limited to one weekly broadcast for Swiss citizens in each continent separately. The programmes intended for the Swiss were of a homely popular character, but for foreigners an endeavour was made to convey a rounded-out conception of Switzerland's artistic achievements, of her general activities and of her age-old ideals. The talks were enhanced by samples of Swiss musical art, popular music with the more stately and the classical with the modern. Unfortunately, when the first station was practically finished it was burnt down.

The new Swiss station is now well on the way to completion. It is situated at Schwarzenburg, about twenty kilometres from Bern. The construction of a short-wave station is a heavy and costly undertaking for a small country of no more than four million inhabitants. The reconstruction of the station without loss of time and in spite of the enormous difficulties of a world crisis is a proof of the tenacity and capacity of Swiss engineers. Until quite recently, the short-wave transmissions have been in the experimental stage. But now rapid progress is being made. It is expected that a regular daily programme will be organized for all continents. The first step will include a one station service only, with two directed aerials for North America, one for South America, two for Africa and one for the Far East. The second step will bring two additional areas for Central America, Southern Asia and Australia, and a circular emitter which will ensure the listeners in bordering European lands of good reception, and in addition a second station will be connected with all these different types of emitters, allowing thus simultaneous transmissions of two programmes on different wavelengths and for different destinations. The station will for financial reasons have to find ways and means of recuperating a part of its investment. To this end, the second transmitter will be placed principally at the disposal of a radio-telephone service with overseas countries.

"Metallurgical Abstracts"

THE Minister of Labour in a recent speech said: "I want to shorten the war. I believe it can be shortened, but nothing but metal will do it". No more emphatic statement of the importance of the metallurgist in the present struggle could be desired. In connexion with all metallurgical work the accessibility of complete and authoritative abstracts of the research work published throughout the world is essential. For many years the "Metallurgical Abstracts" of the Institute of Metals have been widely recognized as fulfilling these requirements, and the latest volume fully upholds the reputation of its predecessors ("Metallurgical Abstracts" (General and Non-Ferrous). Edited by S. C. Guillan. Vol. 6 (New Series), 1939. Pp. xii+683. 1940. London: The Institute of Metals, 4 Grosvenor Gardens, London, S.W.1. Subscription price, including two bound volumes of the *Journal of the Institute of Metals*, £4, post paid). In every metallurgical and most engineering establishments of the country where non-ferrous metals are produced, fabricated or used, this volume is essential.

The *Journal of Pathology and Bacteriology*

WITH the May issue, this journal completes its fiftieth volume. Founded in 1892 by the late Prof. Sims Woodhead, it has consistently maintained its position as an authoritative journal of British pathology, and much of the best work in pathological and bacteriological research of British investigators has appeared in its pages. Commendation must be expressed with regard to paper and type, and the excellent illustrations have always been a feature. The present number which, in spite of war-time restrictions, maintains the high standard of its predecessors, contains thirteen papers covering a wide range of subjects in human and animal pathology, bacteriology, chemotherapy and other topics, together with some shorter articles and book reviews.

University of Iceland

IT is stated by the Reykjavik correspondent of *The Times* that the University of Iceland recently celebrated the twenty-ninth anniversary of its foundation by inaugurating a new university building, erected with the proceeds of a lottery authorized by the State. The British Minister, Mr. Charles Howard Smith, was present, and messages of congratulation were received from the Universities of Cambridge, Dublin, Leeds, London, Oxford, and Abo (Finland), and Yale University. The new building is large enough to house all the faculties of the University, which has until now had to make use of temporary quarters in the Parliament Building.

Announcements

DR. RICHARD KRONER, the well-known German Jewish philosopher and formerly professor at Dresden, Kiel and Berlin, who left Germany two years ago, has been appointed professor of logic and metaphysics at McGill University, Montreal.

THE National Academy of Medicine of Mexico has recently celebrated the centenary of the birth of the Mexican hygienist Edoardo Licéaga (1839–1926), author of works on inoculation against rabies, protection of the ports and frontier cities of Mexico against cholera, and the geography and prevention of yellow fever and typhus.

ERRATUM.—In the leading article on salvage and utilization of waste in NATURE of June 29, p. 988, reference was made to the utilization of woollen rags in the manufacture of high-grade paper. For "woollen" should be read "cotton".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Site of Action of Œstrogens

WE have attempted to determine whether œstrogens act directly on the vagina or whether they have to be absorbed into the general circulation before they can produce their action by the following method. Female mice were operated under ether anæsthesia and the vagina was separated from the bladder and urethra. It was then cut into approximately equal upper and lower parts. The upper end of the lower part of the vagina was sewn up, thus making a small vaginal sac with a normal opening. The lower end of the upper part of the vagina was then drawn up to the region just above the symphysis pubis, and implanted into the anterior abdominal wall. This upper vaginal sac, with an opening into the suprapubic region, was thus entirely separate from the lower vaginal sac. Healing occurred rapidly and a few days after the operation a bilateral ovariectomy was performed. Some ten days later the animals were ready for experiments.

In control experiments, œstradiol in saline was injected subcutaneously and the response of the upper and lower vaginæ were measured quantitatively by the method previously described[1]. The extent of the œstrogenic response was greater in the lower than in the upper part of the vagina, a result in agreement with that obtained by Robson and Wiesner[2] from histological examination of the vagina of ovariectomized mice following the administration of œstrin.

Œstrogens were now injected into the lumen of the upper vagina in doses which are insufficient to produce any appreciable effect when administered by the subcutaneous route. The substances, in solution or suspension in saline, were administered by means of a micro-syringe, with which 0·001 c.c. was given at each injection.

It was surmised that if the œstrogen had to be absorbed from the vagina into the general circulation before any effect could be produced, the response, if any, would be more marked in the lower than in the upper vagina. On the other hand, if the œstrogen could act locally without absorption into the general circulation, it might well produce a marked effect in the upper vagina without affecting the lower vaginal sac.

Œstrogen	Total dose given (μ gm.)	Site of injection	Average scores of vaginal responses		No. of animals
			Upper vagina	Lower vagina	
Œstradiol	0·1	Subcutaneously	5·0	7·5	4
Œstradiol	0·25	,,	6·0	8·4	5
Œstradiol	0·005	Upper vagina	2·7	0	4
Œstradiol	0·01	,, ,,	6·6	0·9	15
Stilbœstrol	0·01	,, ,,	5·9	1·3	7
Stilbœstrol	0·2	,, ,,	11·4	0·4	9
Œstriol glucuronide	5·0	,, ,,	7·3	1·2	15

The results are shown in the accompanying table. It will be seen that all three œstrogens used, namely, œstradiol, stilbœstrol and œstriol glucuronide produced some degree of cornification when injected into the upper vaginal sac and that there was practically no effect in the lower vagina. The results obtained with stilbœstrol were especially striking, since the administration of 0·2 μgm. of this substance into the upper vagina produced very marked effects, four out of the nine animals showing complete cornification, while the lower vaginæ were practically completely unaffected. These results thus show that natural and synthetic œstrogens can act locally without absorption into the general circulation.

Emmens and Ludford[3] have recently shown that œstrogens produce no effect on the vaginal epithelium in tissue culture and have suggested, like Hechter, Lev and Soskin[4], that the effects of œstrogens may be dependent upon the production of hyperæmia. The present experiments are in no way in disagreement with such a hypothesis, since the local response to œstrogens occurred in the presence of an intact vaginal blood supply.

The local response to œstriol glucuronide is also of interest since it shows that either the vagina can respond to conjugated œstrogens or that the compound can be split locally in the vagina.

Gluten Protein

THE validity of Osborne's conclusions[1] that gluten is made up of the two proteins, glutenin and gliadin, has been rendered doubtful by more recent work, but no general agreement as to the true nature of the material has been reached. The work of Krejci and Svedberg[2,3] using the ultracentrifuge, and of Lamm and Polson[4] using diffusion suggested that more detailed studies using these methods would contribute greatly to solving this problem. Such studies have been in progress in Uppsala during the past winter. It has been considered essential to include as much as possible of the whole gluten protein in these studies, and as sodium salicylate has previously been shown to be the most generally satisfactory dispersing agent for gluten[5,6], this solvent has been used almost exclusively.

Two series of results are of primary importance. First, the dispersing power of sodium salicylate is directly proportional to its concentration up to 8 per cent. This had already been determined[7], but concentration calculations from the ultracentrifuge diagrams show that only part of the protein dispersed is in true molecular solution. The crude dispersions, even after the complete removal of starch, are opaque. This opaque material is rapidly sedimented out at a relatively low speed in the ultracentrifuge, as is some of the protein in the clarified dispersion. About 35 per cent of the gluten protein was dispersed in 2 per cent salicylate, but less than half of this (14 per cent) was in molecular solution. Dispersions of a soft wheat gluten in 2, 4, 6, 8, 10, 12 and 16 per cent sodium salicylate were ultracentrifuged at 65,000 r.p.m. (centrifugal force about 300,000 times gravity). The percentages of the gluten protein found to be in true solution were 14, 34, 48, 68, 72, 84, and 77 respectively. This relation is approximately linear up to 8 per cent, the point at which dispersion is virtually complete[7]. The sedimentation constant (s_{20}) of the molecularly dispersed protein was nearly constant at about 2·5. (Sedimentation constants are given in units of 10^{-13}, and diffusion constants in units of 10^{-7}.) Some of the protein that sedimented out of solution at low concentration of salicylate was molecularly dispersed in higher concentrations, and yielded the same s_{20} values as the more soluble fractions. This fact was verified by fractionating the protein into four fractions and subjecting each to ultracentrifuge studies. The s_{20} values obtained were the same for all fractions, but the percentage of the protein molecularly dispersed decreased with decreasing solubility of the fractions.

The second series of results was obtained by diffusion[4]. Gluten protein was clarified in a low-speed ultracentrifuge at 12,000 r.p.m. (centrifugal force about 10,000 times gravity) and fractionated to yield four fractions on the basis of solubility. The diffusion constant (D_{20}) of each fraction was determined and found to be 2·14, 3·13, 4·12 and 4·83 for the four fractions, starting with the most insoluble. The fractions were recombined and the diffusion constant of this material was 3·36, in good agreement with the weighted mean of the results for individual fractions, which was 3·32. The diffusion curves showed that each fraction was itself highly inhomogeneous, and the values of diffusion constants given are mean values. These results are substantiated by the use of the equilibrium centrifuge. The mean molecular weight of the most soluble fraction (23 per cent of the total gluten) was 44,000, this value being obtained by both the sedimentation-diffusion method, and the equilibrium method[8]. The weights of the other fractions were much higher and increased progressively with decreasing solubility.

Considering the two series of results together it is at once obvious that the shape of the molecules in the different fractions must be very different. The molecules are undoubtedly long and thin, and it seems certain that the dissymmetry increases as solubility decreases. It also seems certain that there are many lengths of molecules, and that the theory of two, and only two, distinct and different proteins, 'glutenin' and 'gliadin', in the gluten, must be rejected. The suggestions of Sandstedt and Blish[9] and of Blish[10] that there are three or only a few rather distinct components do not seem to fit the present results any better. (Studies on acetic acid dispersions also showed gluten to be inhomogeneous.) The hypothesis advanced in earlier papers[7,11] that the gluten protein is a protein system made up of components varying regularly and systematically in chemical and physical properties is strongly supported by the present work.

Full details of this research will be published in the *Canadian Journal of Research*. We wish to thank Prof. The Svedberg, Uppsala, for providing facilities for carrying out the studies. The expenses incurred at the Institute of Physical Chemistry, Uppsala, were defrayed by grants from the Rockefeller and Wallenberg Foundations. The salary of the senior author was paid by the National Research Council of Canada, and other expenses were supplied by the Searle Grain Co., Ltd., Winnipeg.

Production of Oxygen by Illuminated Chloroplasts

THE activity of isolated chloroplasts in light, measured by the oxygen evolved from ferric oxalate, has been shown to be relatively high. The ferric oxalate is reduced to ferrous oxalate and oxygen, which is equivalent to the iron reduced, and was measured by means of hæmoglobin. The maximum pressure of oxygen obtainable, however, was only 4 mm. mercury[1,2]. It has now been proved, by direct measurement of the oxidation of ferrous oxalate, that this low limit of oxygen pressure obtainable simply results from the re-oxidation of the ferrous oxalate produced by the illuminated chloroplasts. If the oxygen uptake due to the oxidation of the ferrous salt can be prevented, oxygen should accumulate to a higher pressure and be capable of direct measurement. It was found that ferricyanide rapidly oxidizes ferrous oxalate in the presence of excess of potassium oxalate.

Potassium ferricyanide does not itself produce oxygen with the chloroplasts in light. But when a mixture of potassium ferricyanide and ferric potassium oxalate is illuminated in the presence of chloroplasts, molecular oxygen is evolved at a pressure above the atmospheric. The gas evolved was proved to be oxygen by Krogh's method. Experiments were then carried out in Barcroft manometers at 20° C. and the rate of oxygen evolution determined. The results are shown in the table below, and were obtained as follows. The experimental fluid contained the chloroplast suspension in sucrose $M/5$, potassium oxalate $M/2$, potassium ferricyanide $M/10$, ferric oxalate $M/500$, and phosphate buffer pH 7·0 $M/15$. 5 c.c. were introduced into each cup of the manometer with 10 per cent caustic potash in the centre pot. The left cup was darkened while the other was illuminated from below with approx. 10,000 lux. The concentration of chloroplasts is expressed in terms of the dry weight of the whole leaf from which they were obtained.

Stellaria media.	Dry weight 43 mgm.
Q_{O_2} 7–15 min.	7·8
,, at 40 ,,	1·8
Total O_2 at 40 ,,	143 c.mm.
Chenopodium Bonus-Henricus.	Dry weight 49 mgm.
Q_{O_2} 7–15 min.	8·9
,, at 30 ,,	5·8
Total O_2 at 30 ,,	199 c.mm.
Chenopodium Bonus-Henricus.	Dry weight 4·9 mgm.
Q_{O_2} 7–15 min.	17·8
,, at 30 ,,	4·3
Total O_2 at 30 ,,	33 c.mm.

The maximum Q_{O_2} obtained is 18, compared with a Q_{O_2} of 20 as originally measured by hæmoglobin. These new findings confirm the former experiments carried out with hæmoglobin as a means of measuring oxygen, and in addition show that the isolated chloroplast in light can evolve oxygen at a high pressure. The chloroplast then, with ferric oxalate as a hydrogen acceptor, behaves in a similar way to the whole cell as regards the production of oxygen during photosynthesis.

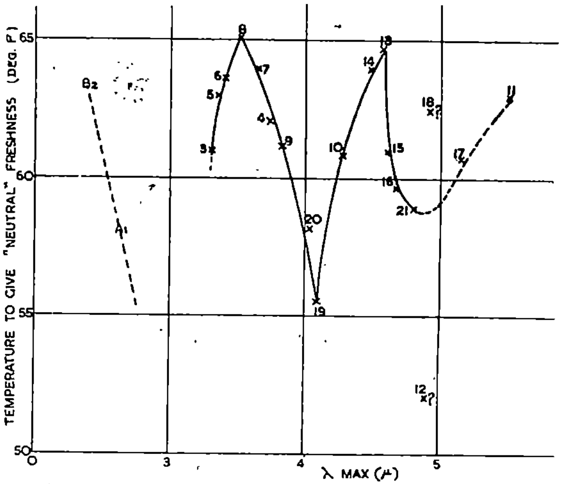
Radiation and 'Stuffiness'

WHILE difficult to define, the sensation of 'stuffiness' is easily recognized subjectively by everyone. Since the sensation can be caused by overheating, it is essential in work on stuffiness to make sure that the human subjects of the experiment are comfortable as regards warmth.

Following the procedure of earlier investigations in the field of human comfort, a numerical scale, the substantial linearity of which has been demonstrated statistically, was allotted to the various comments on sensations of stuffiness and freshness expressed by the subjects. The reactions of 'sessions' of about ten people each, tested separately, could then be averaged. By such methods it has been shown that sensation of stuffiness increases, *ceteris paribus*, with air temperature, according to a definite smooth curve.

An experimental gas fire has been built consisting of a blackened iron plate 14 in. × 16 in. with nine chromel alumel thermocouples embedded in it at strategic points. Its temperature can be varied over a wide range by control of the gas rate, and can be measured by means of the thermocouples. Spectrometric investigations have shown that the fire approximates to a 'black' or 'grey' body, and confirmed the wave-lengths of maximum energy calculated from temperature measurements.

Although in an incomplete state because of the War, the results so far obtained may be of interest. They suggest that 'stuffiness' is associated with values of λ max. of about 3 μ, 4·1 μ and 4·8 μ, with regions of freshness in between, as shown in the accompanying graph; where a low temperature for 'neutral' freshness, that is, neither fresh nor stuffy, means a wave-length associated with stuffiness and vice versa. With the longer wave-lengths, the quantity of radiation is smaller, the subject nearer to the fire, and therefore less evenly warmed by it, and the results more erratic. The numbers of the points indicate the order in which they were obtained.



RELATION BETWEEN SENSATIONS OF FRESHNESS AND STUFFINESS AND PEAK WAVE-LENGTH OF RADIATION. TOTAL, MORE THAN 200 VOTES. POINTS *A* AND *B* WERE OBTAINED WITH A DIFFERENT TYPE OF FIRE. - - - -, PORTION OF CURVE NEEDING FURTHER DATA.

Sir Leonard Hill[1] has given reasons for believing that nose closing, which may be a cause of stuffiness, is associated with radiation which does not penetrate the stratum corneum, though his views are not yet generally accepted[2]. Taylor[3] has given data on the infra-red absorption spectrum of the stratum corneum, showing the hydroxyl group absorption bands at about 3 μ, 4·7 μ and 6 μ. It is tempting, therefore, to associate the stuffiness bands at 3 μ and 4·8 μ with the absorption bands at 3 μ and 4·7 μ. Examination of Taylor's curves suggests that the use of a narrower spectroscope slit (he used 0·01 in.) might show an absorption band between 4·1 and 4·2 μ. Preliminary experiments have increased the probability of an absorption band at 4·15 μ.

Types of Californian Miocene Foraminifera

Following upon the review by "A.M.D." of Dr. R. M. Kleinpell's monograph on "Miocene Stratigraphy of California" in Nature of December 23, 1939, p. 1030, it may be of interest to note that the topotype material with the actual described types referred to by the author of the above work have now been deposited by me in the micropalæontological collection of the Stanford University.

On p. 21 Dr. R. M. Kleinpell refers to my contribution, "Foraminifera from the Tertiary of California", 1900, *Proc. Calif. Acad. Sci.*, Geol., 1, 241–258, pls. 29, 30 (1900) as the first description of Californian Foraminifera, as follows:

"Topotype material from Chapman's locality has not been obtained. As it is impossible to examine his original material, all synonymy is based on comparisons with his figures".

At the time of publication (1900) I was in communication with Dr. J. C. Merriam—who had forwarded me the foraminiferal marl through my late friend, Prof. Rupert Jones—with regard to depositing these original types in a permanent museum in America. On my removal from London to Melbourne, to take up the position of State palæontologist, I was apparently lost to sight or memory by the American palæontologists concerned, although actively publishing in the meantime. It was only lately, however, since the publication of Dr. Kleinpell's work, that I have been able, through him and Prof. Hubert G. Schenck, finally to deposit the types of this original sample, which have now a historic interest, labelled "From a well in Santa Clara Co., California" in the Stanford University.

Inter alia, may I point out that by an oversight the reviewer remarks that in the above work of Dr. Kleinpell's "there do not appear to be any new species", whereas that author has described sixty-six new species and varieties.

Frederick Chapman.

Crohamhurst,
17 Threadneedle Street,
Balwyn, E.8,
Melbourne.

I acknowledge the correction in Mr. Chapman's last paragraph of an unfortunate error, partly due to (though not excused by) the want of any typographical distinction in Kleinpell's book between new specific names and others.

A. M. D.

Phosphate Separation in Qualitative Analysis

In ordinary elementary qualitative analysis, it is usual to remove phosphoric acid from solution as ferric phosphate by dropwise addition of ferric chloride under certain conditions after removal of Group I as chlorides and Group II as sulphides. Zirconium phosphate is well known to be insoluble in acid solution and it appeared that, as an alternative method, phosphoric acid might be removed by addition of a soluble zirconium salt. The following scheme has been found to work well with elementary students in our laboratories.

As usual, the filtrate from Group II is boiled until free from hydrogen sulphide and a few drops of concentrated nitric acid are added. An acid solution of zirconium nitrate is added dropwise until further precipitation ceases; the whole is warmed and the insoluble zirconium phosphate filtered off. To the filtrate a further drop of zirconium nitrate is added and, if no precipitate forms, all the phosphate has been removed. Ammonium chloride and hydroxide are now added as usual, *the solution well boiled* and filtered.

The *filtrate* will contain any members of Group IV (Zn, Mn, Ni, Co), Group V (Ca, Sr, Ba) and Group VI (Mg, etc.) originally present and may be proceeded with in the ordinary way.

The *precipitate* contains the excess zirconium with any iron, chromium or aluminium originally present. It is boiled with sodium hydroxide, which extracts any aluminium; on filtration the filtrate is neutralized with acid and aluminium precipitated as usual with ammonia. The residue, if coloured brown, contains iron. In any event, water and sodium peroxide are added to oxidize the chromium, which passes into solution as chromate. After filtration the insoluble portion is extracted with dilute acid and the presence of iron confirmed.

The presence of chromate in the filtrate should likewise be confirmed lest any titanium in the zirconium salt should yield coloured pertitanate, which might either be mistaken for or serve to mask any chromate.

The foregoing method appears to be somewhat more straightforward than the usual procedure and is more easy to explain chemically to the elementary student than the usual method.

A disadvantage lies in the cost of the pure zirconium nitrate solution. But as zirconia is relatively inexpensive, and the presence of hafnium is immaterial, since it behaves exactly like zirconium in these reactions, it should not be difficult to place suitable solutions of the nitrate on the market at a reasonable cost, provided a sufficient demand arose.

It is, of course, important that the zirconium salt shall be pure. By spectroscopic analysis we have invariably found aluminium to be present both in zirconia and in various zirconium salts purchased from reputable firms. In our experiments, therefore, a solution of the nitrate was boiled with excess sodium hydroxide, the precipitate washed repeatedly by decantation and allowed to settle over night. The suspension was then dissolved by warming with half its volume of diluted nitric acid (1 : 1) and the resulting solution was ready for use.

Swelling of Wood Charcoal: Experiments with a New Silica Extensometer

An all-silica extensometer was made to the senior author's design by E. L. Mays, with the object of overcoming certain difficulties encountered in the measurement of the linear expansion of wood charcoal by means of the metallic extensometer pre-

TABLE 1.

Charcoal used	Outgassing temperature	Differential temp. coeff. between silica and charcoal	Saturation values		
			'S' $\frac{\text{gm. alcohol}}{\text{gm. charcoal}}$	% Expansion X $273/T$	Molecular expansion $MX/S \times 273/T$
α	1000° C.	—	0·147	0·139	28·7
β	560° C.	$2{\cdot}82 \times 10^{-6}$	0·121	0·377	92·9
γ	400° C.	$7{\cdot}02 \times 10^{-6}$	0·144	0·704	180·0

TABLE 2.

Charcoal	s/S	$\log p/P$	$x \times 273/T$	x/x_{α}	$d(Mx/s)/dx$	S	$d(Mx/s)/dx \times S$
α	0·90	$\bar{1}{\cdot}50$	0·113	1·0	150	0·147	22·1
β	0·90	$\bar{1}{\cdot}39$	0·227	2·0	225	0·121	27·2
γ	0·90	$\bar{1}{\cdot}39$	0·394	3·48	230	0·114	26·2
α	0·80	$\bar{1}{\cdot}085$	0·064	1·0	205	0·147	30·1
β	0·80	$\bar{2}{\cdot}930$	0·128	2·0	260	0·121	31·4
γ	0·80	$\bar{2}{\cdot}930$	0·210	3·28	282	0·114	32·1

viously described by Bangham and Fakhoury[1]. The most important drawbacks to the metallic form are the risks accompanying outgassing at high temperatures, the difficulty of measuring the expansion on the adsorption of gases and vapours at temperatures as low as that of liquid air, and the need for investigating the expansive properties of the fatty acids, which would attack the extensometer itself.

The new form functions without knife edges by means of a plane silica spiral sealed in a vertical position from its outer end to the body of the extensometer, while its centre is directly sealed to the base of a long pointer through a U-shaped rod. The pointer moves freely in a vertical plane when subjected to a downward pressure on its base. The charcoal rod is mounted between two claws; the upper one rests against a fixed point on the body of the extensometer, while the lower one presses on the horizontal base of the pointer. The movement of the free end of the pointer is read on a calibrated scale by means of a cathetometer reading up to 0·01 mm. A special calibrating device in the form of a micrometer screw gauge was made reading up to 0·005 mm. to determine the magnification of the extensometer at different scale divisions. The magnification was about thirty times, and it proved to be uniform over a wide range.

Comparative experiments on the expansion of a certain piece of charcoal on immersion in methyl alcohol were made by both the metallic and silica extensometers, which proved the correct behaviour of the latter.

Preliminary experiments were made to test the expansive properties of gases and vapours at the temperature of liquid air. Methyl alcohol caused an expansion which amounted to at least half its value at 18° C. (0·58 per cent), though it was still far from saturation. Hydrogen, on the same piece, gave a fairly measurable expansion which increased gradually with the increase of pressure, amounting to 0·115 per cent at atmospheric pressure. Carbon dioxide, however, seemed to give no expansion at liquid air temperature; but it gave an expansion amounting to 0·42 per cent at − 78° C.

Expansion experiments were also made on formic acid. A certain piece of charcoal (γ), which gave a linear expansion of 0·704 per cent by saturated methyl alcohol vapour at 0° C., gave an expansion of 0·923 per cent on saturation with formic acid vapour at the same temperature. Unfortunately the sorption values could not be calculated with the present data at hand owing to the variation in the degree of association of formic acid molecules at different vapour pressures. As soon as these are obtained, the molecular expansion values will be available.

Measurements of the linear expansion of some wood charcoal specimens, supplied by Messrs. Becker and Co., on the adsorption of methyl alcohol revealed some interesting results. Tables 1 and 2 show some of the results obtained for three pieces of the above variety. Those of charcoals "β" and "γ" were obtained by the silica extensometer, while those of charcoal "α" were obtained by a metal extensometer, the magnification of which was 130.

It can be seen from Table 1 that:

(1) With the rise of outgassing temperature, the molecular expansion of charcoal seems to decrease. Such an observation needs further verification on one and the same piece of charcoal, differently treated, a problem which is under investigation.

(2) The charcoal which has a higher temperature coefficient seems to give bigger expansion on adsorption.

It was previously shown by Bangham and Fakhoury[2] that the slope of the molecular expansion curves at high relative pressures, $d(Mx/s)/dx$, is a measure of B/Σ, where B is the incompressible cross-sectional area per gm. mol. of the adsorbate, and Σ is the available adsorbing surface. Now for the same adsorbate, we expect B to be the same at the same relative concentration, (s/S), for the different specimens of charcoal, and Σ to be proportional to the saturation adsorption values S. Therefore, the slopes of the different molecular expansion curves at the same relative concentrations would be expected to be inversely proportional to the saturation adsorption values, that is, $d(Mx/s)/dx \times S$ should be constant, an expectation which is fairly justified by the figures in the last column in Table 2.

The data in Table 2 are taken from the molecular expansion curves, semi-log. isotherms and $\log p - x$ curves for the three above-mentioned specimens of charcoal.

It is also satisfactory to see, from column 5, that within the range shown the ratio of the percentage expansion of the three charcoals remains constant at the same s/S.

In conclusion, we may add that the molecular expansion of charcoal by a series of esters is also under investigation.

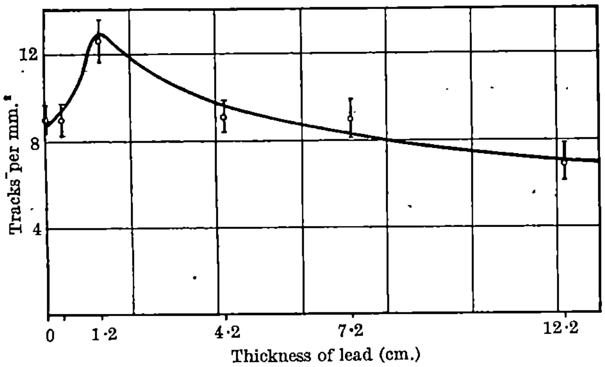
Absorption of Heavy Cosmic Ray Particles

IN a previous note[1] we have described experiments with the object of obtaining information about the radiation producing the heavy particles in the cosmic rays. A set of Ilford half-tone plates (70 μ thick), sensitive to α-particles and protons and covered with thicknesses of lead up to 12·2 cm., have been exposed to cosmic rays on the Jungfraujoch and at Bristol for a period of 230 days. It was found that the primary radiation producing the tracks is strongly absorbed in air, but very little absorbed in lead, and it was concluded that the majority of tracks observed in the emulsion are produced by the neutron component of the cosmic rays.



VARIATION OF NUMBER OF HEAVY TRACKS WITH THICKNESS OF ABSORBER.

We have now measured the absorption curve in lead, on the Jungfraujoch material, in more detail and with greater accuracy. The result is shown in Fig. 1, where we have plotted the number of tracks per mm.² against the thickness of lead. Only tracks with a visible range greater than 10 cm. air equivalent have been included since a large fraction of the shorter tracks are due to radioactive contamination. The curve shows a maximum at about 1·2 cm. lead.

It follows from this result that there are at least two components of cosmic radiation producing heavy tracks. The first component is very little absorbed in lead and consists very probably of neutrons. The second component has a transition curve in lead very similar to that of the soft radiation. It has a maximum coinciding precisely with the Rossi maximum and falls rapidly to a small value within 5 cm. of lead. We therefore conclude that the soft radiation (electrons and light quanta) is responsible for part of the heavy tracks and particularly for the maximum of our curve. It is plausible to assume that the process by which these tracks are produced is the direct nuclear photo-electric effect.

The cross-section for this photo-electric effect can only be estimated very roughly from these results for several reasons. First, the number of light quanta per cm.² min. at the Jungfraujoch is not known accurately. Secondly, since most of our tracks are passing through the whole emulsion, we do not know the actual distribution of range of our particles and, consequently, we do not know whether the bulk of our tracks originate from the lead or from the glass.

The number of soft ionizing particles at the Jungfraujoch is about 2 per cm.² min. After cascade multiplication in 1·2 cm. lead, we can assume that the number of light quanta with energies greater than 10 Mev. is about 6 per cm.² min. Assuming, further, an average range of the disintegration protons of 1 m. air equivalent, we find an average cross-section for photo-disintegration with proton emission of 10^{-25} cm.² per lead atom or SiO_2 molecule. This figure is very rough and may well be wrong by a factor 5. We may compare it with the cross-section for the photo-electric effect with neutron emission obtained by Bothe and Gentner[2] for copper and the lithium γ-rays, namely, 5×10^{-26} cm.². Our figure may seem to be rather large, especially in view of the fact that neutron emission is much more probable than proton emission, but taking into account the many uncertainties involved, it is probably a reasonable order of magnitude.

If it is true that some of the protons are produced by photo-electric effect, it must be expected that an even larger number of neutrons is produced in the same way. Since we do not know the cross-sections for the photo-electric effect for oxygen and nitrogen atoms, it is difficult to decide whether the whole neutron component of cosmic radiation can be accounted for by a photo-electric effect taking place in the high atmosphere, or whether other processes are involved in the production of the neutron component too (compare also ref. 3).

Further details will be published elsewhere.

Specific Ionization of Cosmic Ray Particles

MEASUREMENTS of the specific ionization of cosmic ray electrons with energies between $0 \cdot 1 \times 10^6$ ev. and 30×10^6 ev. have been made by Corson and Brode[1] by counting droplets on photographs taken with a counter-controlled cloud chamber using a delayed expansion. They established the existence of a minimum ionization at about $1 \cdot 5 \times 10^6$ ev. and a logarithmic increase in ionization with energy beyond this minimum. Using essentially the same method, I have measured the specific ionization of cosmic ray particles over the energy range $2 \times 10^6 - 6 \times 10^9$ ev.

The track photographs were classified in the following way:

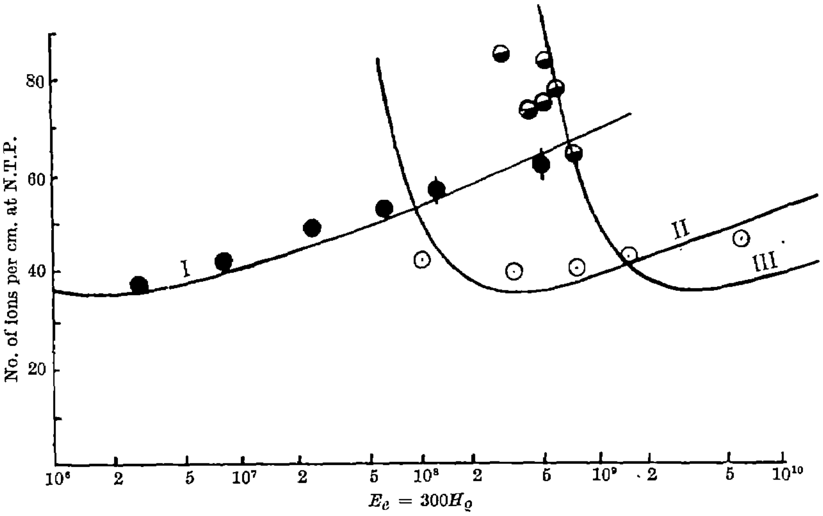
(1) In general, all particles in showers were assumed to be electrons. The exceptions were a few particles of energy greater than 10^8 ev. which showed an ionization markedly less than that of electrons of the same energy, and were therefore considered to be mesons responsible for the production of 'knock on' showers. Three particles, each from a separate shower, were taken as mesons out of forty measured showers for this reason.

(2) Single particles with energy less than 40×10^6 ev. not exhibiting heavy ionization were taken as electrons. Mesons of this energy would be recognizable because of their heavy ionization.

(3) Single particles in the energy region 2×10^8 ev. to 7×10^8 ev. showing markedly heavy ionization were taken as protons.

(4) All other single particles were assumed to be mesons, although certainly a small fraction were protons.

The theoretical curves for electrons, mesons ($M = 170\ m$) and protons are shown in the accompanying graph. The experimental results for electrons show good agreement with the theory over the



ENERGY IONIZATION CURVES FOR ELECTRONS (I), MESONS (II), PROTONS (III).

● = ELECTRON
○ = MESON (M = 170 m)
◒ = PROTON

observed range, that is, between 2 × 10^6 ev. and 5 × 10^8 ev., both as regards absolute value and variation with energy.

For mesons, the agreement with theory is not as good. However, the results do show a small rise of ionization with energy, though not as much as is expected. Possibly the errors of the curvature measurements may be the cause of this discrepancy. Since the protons above 2 × 10^3 ev. ionize less than mesons of the corresponding energy, the relatively low observed value in the highest energy group may possibly be explained as due to some protons being included in the group. Unfortunately, no meson track was observed with a momentum low enough to allow a reliable mass determination.

Among 3,000 tracks, eight recognizable proton tracks (all positive) have been observed. The observed values of the mean specific ionization on each individual proton track are shown as half-shaded circles, and show a satisfactory agreement with the theoretical curve. No alpha particles or other multi-charged particles were observed, nor any deuterons.

A detailed account of the investigation will be published elsewhere.

Current Distribution and Throwing Power in Electrolytes

THERE are two interesting aspects of the distribution of a direct current flowing between soluble metal electrodes in an aqueous electrolyte confined in an insulating vessel. Theoretically the problem appears to be soluble, ideally at least, by classical potential theory using the electrochemical theory of the anode and cathode fall. The distribution is of great practical importance in attaining uniform deposits on curved surfaces and in holes, and in avoiding heavy deposits on sharp edges and projections.

Although the current distribution between a common anode placed between two equal cathodes at the same potential but at variable spacing has been extensively investigated experimentally, G. E. Gardam[1] appears to be the first to attempt a theoretical treatment. He showed that the ratio of the currents flowing to each cathode can be calculated in terms of the dependence of the cathode fall on the current density, the conductivity of the electrolyte, and the electrode spacings, for the case of a uniform field corresponding with the experimental arrangement of Haring and Blum[2]. This theory also predicts the relation between the cathode currents and the throwing power[3], which latter is a function of the ratio of the weights of the deposits and the electrode distances. A good agreement is reached with both his own experimental results and those of other investigators.

Recently the current distribution in electrolytes for various electrode systems giving non-uniform fields has been examined theoretically by C. Kasper[4] by applying potential theory; the important effects of potential falls at the electrodes are, however, neglected.

A new theoretical and experimental investigation of the current distribution between plane electrodes at variable spacings in a non-uniform field has been carried out in an attempt to remedy this defect. The experimental arrangement consists of an anode, a main cathode with a hole in the centre from which, on the side opposite to the anode, a rubber tube extends, ending in a small subsidiary cathode (at the same potential as the main cathode). The current to the subsidiary electrode is calculated approximately from the sum of two potential terms. The first is the potential at the centre of the hole determined by the potential field between the three electrodes; this field problem is similar to that in a cathode-ray oscillograph[5]. The second is equal to the difference between the two cathode falls. Allowance is made for the resistance of the electrolyte between the two cathodes. Assuming the usual logarithmic relation between the cathode fall and the current density, it is found that the ratio of the subsidiary to the main cathode current decreases with increasing distance between the cathodes and with increasing current to the main cathode, the rate of change being very rapid at small spacings. Furthermore, this ratio is independent of the distance between the anode and the main cathode over a wide range.

Using copper electrodes in neutral and acid solutions of copper sulphate, these theoretical predictions are found to be satisfactorily confirmed by the present experiments, in which measurements of the electrode potential fall by means of probe electrodes are introduced. A detailed report of these investigations will be published later. A. v. ENGEL.

RESEARCH ITEMS

Native Medicine in Portuguese Africa

In a study of native conceptions of disease and healing in Portuguese Africa (Guinea, Angola and Mozambique) by Luiz de Pina (*Scientia*, 67; 1940) it is pointed out how close is the resemblance in basic ideas not only with those of primitive peoples generally, but also of the backward European peasantry. In Portuguese Africa illness may be attributed to any of three causes: (1) the introduction of a strange body or a spirit or soul of another person, often of a sorcerer, into the body of the sick person; (2) the hostile action of a *fetiço* (enchantment) by another person or object; (3) the vengeance or punishment of the gods, idols, etc. While any one of these may be operative, it is the idea of *fetiço* which dominates the native mind. The nature of *fetiço* is incorrectly presented by many writers. It is not merely an object, it also covers a charm, spell, a bewitching, a divination or a curse, and it may cause a tempest, a disastrous war, toothache, illness or any like misfortune. Its author, if a living person, is condemned to death, but the responsibility may rest also with an object, an idol, or a divinity. Usually, however, it is a wizard or witch. These are both loved and execrated according as their powers are exercised in the detection of, or the causing of, *fetiço*. Among certain African peoples the belief in a supreme and inferior deities, represented by idols, more or less crude, may be found, but there, it is to be noted, the powers of the supreme deity are less than those of the spirits controlled by the sorcerers, since the supreme deity exercises no influence over the affairs of this world. Some of the lesser deities are concerned only with certain specific diseases, and some of them are venerated in sacred places and have a priesthood attached to their cult. The practitioners concerned in the medical art are doctors, sorcerers and midwives. The doctor, who is both surgeon and physician, combines with his functions those of the sorcerer, as the sorcerer does those of the doctor. The basis of the healing art is magic, which in the detection and punishment of the individual responsible may be made the instrument of private vengeance. After the sorcerer comes the physician, who among his medicaments draws upon the wide variety of simples and drugs provided by the indigenous flora.

Continuity of Culture in Scandinavia

Two contributions appearing in *Antiquity* of June 1940 deal with Scandinavian cultural survivals from prehistoric or earliest times. A. W. Brøgger sketches the development of Norwegian cultural history "from the Stone Age to the Motor Age". Up to a century ago on a farm was a stone bearing the runic inscription "Eiliv Elg carried fish in Rausjøen", indicating that in the days of Olaf the Holy, as in modern times, fry was transferred to the mountain tarns. Only fragments of the saga from the Stone to the Motor Age have been found; but the lines may be traced in the foundations of folk-culture. Two animals dominated the annual culture, the stag and the seal, supplemented by the elk and the reindeer. The first change was the introduction of domesticated animals and corn four to five thousand years ago. Henceforth peasant culture is a combination of hunting and farming. With the Iron Age, peasant culture incorporated iron production from bog ores and native rock-species, while the introduction of the iron axe provided an efficient weapon against the forest. The foliage knife, which afforded fodder for the cattle, and the scythe are the fundamental elements in the emergence of the Norwegian farm, based upon cattle breeding, which was the social, economic and technical unit, with the family as its active centre. The Iron Age also brought a new type of boat which made possible the development of the maritime culture of the Vikings. A rural industry of Jutland, of which an account is given by Axel Steensberg, produces a hand-made pottery, small black vessels of great beauty which, notwithstanding the introduction of the potter's wheel into Denmark at the close of the Iron Age, has survived down to to-day.

Biology of the Silverfish Insect

An important study of a silverfish, *Ctenolepisma longicaudata*, first described in 1905 from S. Africa, and since found to be widely distributed, has been made by Eder Lindsay (*Proc. Roy. Soc. Victoria*, 52 (N.S.), 35; 1940). The species, which is becoming a pest of increasing importance in Australia, since it feeds upon stored food materials as well as upon paper, cotton and artificial silk, has a life-history spread over about seven years, during four of which it is mature. Its temperature tolerance ranges from 11° C. where development stops and the insect becomes torpid, to an optimum at 25° C., temperatures higher than which cannot long be endured. In dry air silverfish die rapidly, and since they take no liquid, their moisture content is derived from food and oxidation of food-stuffs, as well as from moist air. The rate of egg-laying is low, but the long life of the adults leads to rapid increase in numbers: if each female laid 56 eggs a year and there were no fatalities, the progeny of one pair would lay 470,000 in the seventh year. Control is exercised by toxic sprays which must come in contact with the insect, and is most effective when carried out at night; but the nature of the life-history, feeding habits, and temperature and moisture tolerance, associated with the absence of enemies, suggests that control measures to be reasonably effective must be applied continuously.

Madreporarian Corals of the "Discovery" Expedition

J. Stanley Gardiner describes a small collection from a number of localities of Madreporarian corals with an account of variation in Caryophyllia (*Discovery Rep.*, 18, 323–339; 1939). *Flabellum curvatum*, obtained in seventeen dredgings, was remarkably widely distributed. Although the only common feature in these localities is the low temperature, there was no character found in this species which might be supposed to be related with this factor, and the specimens presented no difference in texture compared with species from the Indian Ocean. Very few positive conclusions emerge from the review of the variation in Caryophyllium, which is a cosmopolitan genus and usually inhabits waters deeper than 50 fathoms. The study of ecological conditions with regard to variation does not help much owing to scanty knowledge of the natural habitats. Fossil forms are common in tertiary deposits and have also been described from the cretaceous. The author regards it as clear that many, perhaps most, fossil forms of Caryophyllia still continue to exist to-day.

Diffusing Factors

DIFFUSING factors which increase the permeability of the skin to injected fluids and particles can be obtained from such diverse sources as spermatozoa, testis, bacterial cultures, malignant tissues, leeches and snake and spider venoms. For example, a mixture of Indian ink and testicular extract is injected intracutaneously into the shaved back of a rabbit and a control injection of Indian ink in saline is also made. The area over which the particles of Indian ink spread is increased by high dilutions of the testicular extract. The passage of substances such as dyes, hæmoglobin and diphtheria antitoxin is influenced by the diffusing factor. Madinaveitia and co-workers, in a series of papers (*Biochem. J.*, 34, 613, 621 and 625; 1940), discuss a possible theoretical mode of action for the diffusing factor. They also show that it can be separated from the proteases of a *Cl. Welchii* filtrate, and find that in a preliminary concentration from testicle powder, mucinase activity seems to run parallel with diffusing factor activity.

Inclusions in the Cells of Virus-infected Plants

F. M. L. SHEFFIELD, of Rothamsted Experimental Station, has published an informative summary of the effects of plant virus diseases on the cells of their hosts (*J. Roy. Micro. Soc.*, 59, 149–161; 1939). Descriptions of normal and diseased cells indicate the general effects, such as the increase in protoplasm content, which often accompany virus attack. Amorphous inclusions are shown to be composed of protoplasm, and to contain oil globules and chondriosomes. They are of two morphological types, namely, granular and amœboid. Crystalline inclusions often accompany the amorphous products. The presence of inclusions indicates a relatively high concentration of virus within the cell. Amorphous inclusions may give rise to the crystalline type, and the review indicates a high probability that virus protein and both kinds of inclusion are really different manifestations of the same thing. The knowledge here collected is useful equipment for the research worker, but teachers of plant pathology will also find it invaluable.

Strawberry Yellow-edge Virus

A SHORT paper by W. F. Cheal in the *Gardeners' Chronicle* of March 2 describes field trials on the planting of strawberries free from yellow-edge virus. Plots in four centres of the Isle of Ely were established at varying distances from existing plantations which contained diseased plants. The virus disease was very rapidly transmitted to those healthy plants which were within a quarter of a mile of the diseased fields, but no transfer took place when they were separated by a greater distance. It therefore appears that the use of disease-free stocks in strawberry-growing areas is useless, unless they are planted an adequate distance, say a mile, from the existing fields.

Cell-Division

E. W. Sinnott and R. Black (*Proc. Nat. Acad. Sci.*, 26, 223–227; 1940) have shown that the orientation of the new cell wall between daughter cells is determined early in the life of the mother-cell by the cell body. They studied vacuolated plant cells and found that from very early prophase the cytoplasm tends to aggregate into a plate of more or less fused strands where the future cell wall will be laid down. They consider that the factors affecting the orientation of the division act on the cell as a whole and not only on the nucleus.

Translocation in Wild Grasshoppers

M. J. D. WHITE (*J. Hered.*, 31, 137–140; 1940) reports the finding of several individuals of *Metrioptera brachyptera* (Tettigonidæ) in the New Forest which possess a reciprocal translocation between two pairs of chromosomes, III and IV. The first individual was found in 1937 and others were found in 1939, therefore the variety has been able to become well established. Usually chromosomes III and IV form separate bivalents, but occasionally a chain of four chromosomes is found. The small proportion of multiple configurations is possibly due to localization of chiasmata normally present in this species.

Polyploidy in Paramecium

TZE-TUAN CHEN (*J. Hered.*, 31, 175–196; *Proc. Nat. Acad. Sci.*, 26, 231–246) shows that different races of *Paramecium bursaria* differ in the size of the micronuclei. These differences are correlated with the chromosome number. Race *Fd* has about 80 chromosomes while others have several hundreds of chromosomes. Polyploidy probably originates from the fusion of the two pro-nuclei during conjugation. No interference with conjugation is caused by differences in chromosome number. After conjugation the two conjugants possess the same number of chromosomes. Animals without micronuclei can conjugate with animals possessing micronuclei. The behaviour during conjugation of *Paramecium bursaria* is analysed. Three animals have been observed to conjugate together at one time, but exchange of pro-nuclei only takes place between two of the conjugants.

Nature of Ore-forming Fluids

IN a Supplement to *Economic Geology* (34, 197–358; 1940), L. C. Graton gives a valuable summary of present knowledge and theory as to the origin, state, composition, migrations and effects of the mobile medium which transports mineral-forming materials and deposits them to form the hypogene epigenetic ores. The survey starts from the arguments and conclusions of Fenner, Bowen, Ross and Schaller in the well-known "Lindegren Volume", and it is shown that widely differing and irreconcilable hypotheses are currently held and are causing confusion at a stage of the science when some clarification might reasonably be expected. Reasons for this situation are suggested, but it is nowhere indicated that one possible reason may be that some ores at least may not originate within the magma which most authors assume to be the unquestioned source. The dominant agent of hypogene ore genesis is thought to be a late-magmatic hot alkaline liquid extract. Derivation by boiling from the normal magma is regarded as quantitatively insignificant. The contrast is emphasized between the confined conditions in depth where magmatic differentiation is supposed to be accomplished and the special superficial conditions where alone observation is possible of magma in action. It is thought that gas is far inferior to liquid for transporting mineral solutes, and pneumatolysis is therefore regarded as of slight importance except close to the surface. The weak point in all hypotheses of ore genesis from magma is the difficulty of suggesting a satisfactory mechanism of separation to account for the observed sequences of ore deposition, and one of the chief merits of Graton's review is that he frankly exposes this and other difficulties wherever they occur.

Crystalline Lactic Dehydrogenase

Straub (*Biochem. J.*, 34, 483; 1940) has added lactic dehydrogenase to the list of proteins having enzyme activity which can be obtained in crystalline form. The reaction: lactic acid + cozymase $\rightleftharpoons$ pyruvic acid + reduced cozymase is catalysed by lactic dehydrogenase, and the purification of the enzyme has been followed by measurement of the oxygen uptake occurring when lactic dehydrogenase is added to a mixture of lactic acid, cozymase, methylene blue, cyanide and flavoprotein, which forms a complete system for oxidizing lactic acid. The enzyme can be extracted from bullocks' hearts with water and adsorbed on to calcium phosphate gel. After elution with pH 7·2 buffer, purification by fractional precipitation with acetone and then ammonium sulphate is carried out. Finally crystallization is accomplished by gradually increasing the concentration of ammonium sulphate from 0·4 to 0·5 saturation. Lactic dehydrogenase is shown not to be identical with malic dehydrogenase.

Directed Valency

The two methods of studying problems of directed valency, namely, the Heitler–London method of localized electron pairs and the Hund–Mulliken method of molecular orbitals, both have the defect of not giving (*a*) all the possible stable electron groups which give rise to directed valency, and (*b*) the possibilities of multiple bond formation. A new method, based on group theory, is put forward in a paper by G. E. Kimbell of Columbia University (*J. Chem. Phys.*, 8, 188; 1940). Any set of equivalent directed valency orbitals is representable by a characteristic symmetry group and, if the operations of this group are performed on the set, a (usually) reducible representation can be obtained, and, from the character table for the particular group, resolution into component irreducible representations can be carried out. Thus the possibility of covalent bond formation in any spatial arrangement of a given electronic configuration can be tested. Moreover, the possibilities of double- and triple-bond formation can also be worked out. Results of calculations of all configurations of from 2 to 8 s, p and d electrons are given. The molecules which are discussed in detail are: H_2O, H_2S, nitrosyl halides, NO_2', $Ag(NH_3)_2+$ and I_3' ions, CO_2, SO_2 (co-ordination number of central atom, 2); SO_3, SO_3'' (co-ordination, 3); XO_4 ions, $SiCl_4$, $Ni(CN)_4''$, $Ni(CO)_4$, ICl_4' (co-ordination, 4); PCl_5, $Fe(CO)_5$, IF_5 (co-ordination, 5); $Fe(CN)_6''''$, $Fe(CN)_6'''$, SF_6, SeF_6, TeF_6, $SbBr_6'''$, (co-ordination, 6); ZrF_7''', and TaF_7'' (co-ordination, 7); $Mo(CN)_8''''$, OsF_8 (co-ordination, 8). For several symmetry types there are no known molecular or ionic examples, and invariably this is because these symmetry types are shown theoretically either to have great instability or to be much less stable than other possible configurations of the same co-ordination. The geometrical arrangements of the various possible electronic configurations are discussed. The structures deduced from this method are in agreement with those ascertained by the usual methods of investigation; but the method is also capable of predicting structures which so far have not been determined experimentally; for example, the OsF_8 molecule should be a face-centred prism, and the unknown ions $Fe(NH_3)_4{+}{+}$ and $Fe(CN)_4''$ should be irregular tetrahedra.

Diborane diphosphine

An interesting compound, described by L. Gamble and P. Gilmont (*J. Amer. Chem. Soc.*, 62, 717; 1940), is diborane diphosphine, $B_2H_6.2\,PH_3$, which is formed from diborane B_2H_6 and phosphine above −30° in the gas, and above −110° in the liquid phase. It is a white crystalline solid which dissociates above −30° into diborane and phosphine, thus behaving differently from the ammine compound $B_2H_6.2\,NH_3$. It dissolves with difficulty in liquid ammonia, and above −60° the solution evolves phosphine; on evaporation a white solid, $B_2H_6.NH_3.PH_3$, probably $NH_4{\cdot}(BH_3PH_2BH_3)$, remains, hence the formula of diborane diphosphine could be written $PH_4\,(BH_3PH_2BH_3)$. The salt-like nature of the compound is, however, not well defined, as it will dissolve in liquid ammonia at −75° without the liberation of phosphine, unlike a true phosphonium salt, which liberates phosphine and forms an ammonium salt.

A Photographic Survey of Galactic Clusters

George Alter has published a paper, the first of a series, describing the method of work with the Mond astrograph of the Norman Lockyer Observatory, Sidmouth, and also the application to N.G.C. 581 (M. 103) (*Mon. Not. Roy. Astro. Soc.*, 100, 5; March 1940). The Mond astrograph has four telescopes for photographic purposes, and a full description of the instrument has already appeared in "Handbook of the Norman Lockyer Observatory". In the standard working scheme, Camera *A* serves for counting star clusters and determination of cluster diameters. Camera *B* is used for the determination of photovisual magnitudes, without colour screen, by using Ilford Hypersensitive Panchromatic plates, which give the photovisual scale almost perfectly. Camera *C* gives the photographic magnitudes by using Barnet Super Press plates. Camera *D* completes the magnitude series for the brighter stars by shorter exposure time. The magnitude determinations are made by exposures of 1h. on the cluster and 1h. on the north polar sequence on the same plate. Camera *B* has a second cluster plate to detect variables, and in this way a source of error is excluded as all photographs are exposed under the same conditions of atmosphere. A detailed account is given of the work, and the results of the investigation of N.G.C. 581 are as follows: Pleiades type, star number 44, angular diameter 6·8′, distance 2040 (± 180) parsecs, linear diameter 4·5 parsecs.

STEREOCHEMICAL TYPES AND VALENCY GROUPS*

THEORY and experiment agree that the arrangements in space of the covalencies of a polyvalent atom, while they are subject, from a variety of causes, to small variations seldom exceeding 5°–10°, tend to conform to a quite limited number of types. Recent developments of mathematical physics have made it possible to calculate how these types are related to the electronic groups occupied by the valency electrons.

It is, however, not always possible to say which these sub-groups are, and it is in any event desirable for the chemist that he should be able to relate the spatial grouping to some more familiar property of the atom. The property here used is the size (in G. N. Lewis's sense) of the valency group of the central atom, and the number of shared electrons which it contains, together with that of the preceding (unshared) electronic group in the atom. The experimental results show the following relations.

When the valency group is less than 8 we have with a covalency of 2 a linear structure (as in Cl-Hg-Cl): with a covalency of 3 a plane structure with equal angles of 120° (BF_3): with 6 electrons of which only 4 are shared, as in the vapour form of stannous chloride, probably a triangular molecule  $Sn\begin{smallmatrix}Cl\\Cl\end{smallmatrix}$.

With a complete octet the arrangement can be either tetrahedral or planar. When the covalency is less than 4 (partially shared octet), it is always derived from the tetrahedron, as in the triangular OH_2 and the pyramidal NH_3. The fully shared 4-covalent octet can be of either form. When the preceding electronic group, n in the grouping (n) 8, is 2, 8, or 18, it is always tetrahedral. In the transitional elements where $8 < n < 18$, it is found that if n is not much more than 8 the structure is tetrahedral, and if it is not much less than 18, planar; but the two series overlap, and for values of n of 13 to 15 and perhaps 16, both forms occur.

When the valency group is 10 with at least 2 of them (the 'inert pair') unshared, the structure of a dicovalent atom (as in $M[I_3]$) is linear; that of the 3-covalent (as in $C_6H_5.ICl_2$) is unknown, while that of the 4-covalent decet is found in the thallous and plumbous compounds to be planar, but in tellurium tetrachloride may possibly be a distorted tetrahedron.

The peculiar 4-covalent duodecet in $M[ICl_4]$ is planar.

Covalency 5. So far as it has been examined (four different types), this has always been found to give a trigonal bipyramid.

Covalency 6. Three structures are theoretically possible: a trigonal prism, a trigonal antiprism, and a regular octahedron. Experimentally the structure is always found to be the octahedron, except in a few giant molecules such as those with the nickel arsenide lattice. The regular octahedron has been found with practically every possible size of the preceding group, as well as with the 'inert pair' of electrons.

A covalency of 7 has been examined in three or four compounds, which have two different structures, one derived from an octahedron and the other from the trigonal prism.

Covalency 8. The only compound examined, $K_4\,[Mo(CN)_8]$, is found (rather unexpectedly) to have a dodecahedral arrangement of the 8 CN groups.

Nearly (but not quite) all the structures can be even more simply related to the size of the valency group by assuming that the mean positions of the electron pairs in this group are the same whether they are shared or not, the structure being linear for 4 electrons, plane symmetrical for 6, either tetrahedral or plane for 8, a trigonal bipyramid for 10, and an octahedron for 12.

---

CONCENTRIC CONDUCTOR TYPE OF HIGH-VOLTAGE ALTERNATORS

A PAPER on "Operating Experience with High Voltage Alternators" by W. D. Horsley, of Messrs. C. A. Parsons and Co., Ltd., which was to have been read and discussed before the Institution of Electrical Engineers, has now been published in the *Journal* of the Institution of April. It was read and discussed before five local centres at various dates, and the discussions at these centres have been included.

The first high-voltage alternator of the concentric type was commissioned in August 1928, the pressure chosen being 33 kilovolts. The earlier history of this machine and its successful operation have been fully described by C. A. Parsons and J. Rosen and was published in 1929 in vol. 67 of the *Journal*. Since it was installed at the North Metropolitan Power Station, it has worked smoothly, the maintenance costs being negligible although the conditions of operation were more difficult than the average in the early years of its life. There are now twenty-one machines of this type in service, and a review of some of the difficulties experienced is first given. The second machine built had an output of 25,000 kw. at a pressure of 33 kv., and was installed in the Brimsdown Power Station in 1932. But after being put into service, a breakdown occurred on the third day owing to the failure of a slot insulating tube and the core. This accident demonstrated the rapidity with which a bar can be replaced in the concentric type of winding. Soon afterwards, improved methods of inspection and testing, including the measurement of the dielectric losses of individual bars, were introduced, and the possibility of a faulty conductor being fitted in an alternator is now very remote.

In November 1933, a flashover took place from the end windings of the alternator to the station frame, and simultaneously a flashover to earth occurred from one terminal on the main oil circuit-breaker controlling the alternator. An examination showed that the path of the flashover in the stator windings passed through at least 4 in. of air, and it was computed that it could only have been caused by an over-potential exceeding 70 kv. The normal operating potential of the winding to earth at the point of the fault was 6·5 kv. When the flash occurred, the alternator was isolated from the transmitting system and had just been excited to normal voltage prior to being synchronized with the main busbars.

The characteristics of the voltage transformers and of the capacitance of the alternator windings and their connecting cables showed that the conditions which gave rise to the phenomenon known as neutral instability were present. It was calculated that the potential of the windings cable and switchgear could build up to 75–100 kv., which agreed closely with the value deduced from the examination of the failure from the available data.

While the satisfactory operating experience with the concentric-conductor winding proves the construction to be sound, investigations following the failure of a joint showed that a number of improvements were possible. A new technique has been developed for the making and insulating of joints. Among other improvements is the use of glass silk as an insulating material. It is also being used in place of cotton or silk for other purposes. It is more durable and will withstand a higher temperature, and the individual fibres, being solid, cannot absorb moisture.

The earthing of systems through a tuned reactor or arc-suppression coil has received great attention in Great Britain in recent years and is being given a trial on a number of systems. As the coil has a comparatively high impedance, circulating currents due to harmonics should be negligible, and therefore it would be permissible to earth the neutral point of a generator by this means.

Experience has shown that the damage which is caused by an earth fault in an alternator is small, as the differential protection trips both the main and the neutral breakers very rapidly, thus interrupting the fault circuit. A fault between phases causes greater damage, as the fault circuit cannot be interrupted, and although the field circuit may be opened rapidly, an appreciable time is required for the main flux to collapse.

Mr. Horsley concludes by emphasizing the trustworthiness of concentric-conductor alternators, and thinks that they have a promising future.

NATIONAL FRUIT AND CIDER INSTITUTE

THE annual meeting of members of the National Fruit and Cider Institute was held at the University of Bristol Research Station, Long Ashton, on June 27.

Chief among the items of interest were exhibits arranged by the Fruit Products Section dealing with methods of using fruit products to alleviate the difficulties occasioned by the sugar shortage. During the War of 1914–18, Prof. B. T. P. Barker organized a scheme for the conversion of apple juice into jelly. This work has been taken up again and extended by Mr. V. L. S. Charley, who has developed methods for concentrating fruit juices by vacuum evaporation. The acid content of the raw juice is first reduced by the use of potassium carbonate or pure chalk at a rate of 2–3 lb. per 100 gallons of juice. Acid cooking apples as well as dessert varieties can thus be converted into very sweet concentrates. The apple flavour is retained by recovering the volatile products during concentration and returning them to the concentrate. Treatment of the juice before concentration with a pectin-decomposing enzyme allows a high degree of concentration without danger of gelling, and the final product assumes the consistency of treacle, containing about 75 per cent soluble solids and 65 per cent invert sugar. One ton of cull apples produces 150 gallons of juice, which is concentrated to make 13 gallons of treacle.

Apple treacle has been successfully used as a sweetening agent for both domestic and industrial preparations such as jams, cakes, confectionery, cider and pickles. All kinds of excellent jam have been made by using half the normal amount of sugar with an equal quantity of apple treacle. The treacle itself is self-sterile and can be stored without special containers. Apple jelly is made by warming the concentrated juice with one tenth its volume of liquid apple pectin and adding a small amount of sugar. Plum concentrate has also been prepared, but its high acidity renders it less suitable for general use. A fuller account of this work appears in *Food Manufacture*, 15, 6 (June 1940) and in the Long Ashton Annual Report for 1939.

Another exhibit showed methods of maintaining the natural sugar in cider. The usual procedure is to allow the apple juice to ferment and to add sugar to the final product. By adding potassium metabisulphite as a source of sulphur dioxide and removing yeasts by centrifuging, fermentation can be suspended and much of the original sugar content retained.

A phase of the Station's work on plant nutrition was represented by an exhibition of vegetable and other crop plants suffering from manganese deficiency. This deficiency, recognizable by a chlorotic condition and yellowing of the foliage, has occurred with some frequency in oats sown on newly ploughed grassland, especially on highly calcareous soils. Garden beets, spinach beet, spinach, parsnips and lettuce have been found showing similar symptoms when grown in soil to which much lime and organic matter has been added. Successful control is being achieved in some cases by spraying the foliage with a dilute solution of manganese sulphate.

The Station plantations were open for inspection by the visitors. Considerable interest was shown in demonstration plots on which the cropping plans recommended in the Ministry of Agriculture Grow-more Bulletin No. 1 are being subjected to practical tests.

THE ENGINEERING FOUNDATION

THE annual report for 1938–1939 of the Engineering Foundation of New York forms an interesting record of a year's activity in a wide range of research projects mainly of a technical nature, associated with engineering and designed to produce results of practical value to science, industry and public welfare. These researches are carried out in collaboration with engineering and other societies and the results are published by the institutions concerned and by the technical press. The part played by the Engineering Foundation is that of receiving applications for assistance, examining the merits of the projects submitted, recommending and making grants and maintaining contact with the work while in progress.

The present report records a number of researches undertaken and in progress in conjunction with seven other corporate bodies dealing with such important subjects as soil mechanics, critical pressure steam generation, cotton seed processing, and plastic flow of concrete. On the non-technical side, the Engineers' Council for Professional Development was supported in the establishment of central and local committees to deal with such matters as the selection and guidance of engineering students, engineering schools, professional training and professional recognition, the general trend and purpose of the labours of which is towards the raising of the status of the engineering profession.

The Engineering Foundation was established in 1914 "for the furtherance of research in science and engineering or for the advancement in any other manner of the profession of engineering and the good of mankind" and has now completed twenty-five years of useful service. The occasion is celebrated by the issue of a more comprehensive record of the work done during this period which gives particulars of no less than seventy-three major researches and projects which have received grants towards a total cost of more than three million dollars. This is a very remarkable result, more particularly when it is considered that the whole machinery had to be set in motion in the early years of the period. Of the grants made, a substantial portion has been devoted to matters associated with engineering instruction and the promotion of summer schools.

The report concludes with a statement of the increasing need for research. The policy of the Board has all along been one of giving aid to promising projects which otherwise would not have been undertaken because they did not fit into the programmes of other research agencies or because of lack of sufficient funds. Universities have the facilities for investigation but there may be no funds for a particular inquiry. On the other hand, scientific societies may have funds available but be without any research facilities. Again, an industrial concern may hesitate to undertake an investigation the results of which would be used by the whole industry. Such cases provide the kind of opportunity for which the Engineering Foundation exists, in order to deal with the problems and to promote their solution. Much as has been accomplished by the prudent use of the income derived from its endowments, much more remains to be done and the opportunities for productive research are constantly increasing. The Board of the Engineering Foundation looks forward to giving assistance in the work of the future and, by the help of further endowments, to be able to extend the range of its work and its grants.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DIRECTOR OF EDUCATION—The Town Clerk, Town Hall, Stretford, Lancs. (endorsed 'Director of Education') (July 20).

DEMONSTRATOR IN PHYSICS—The Dean, Medical School Office, Guy's Hospital, Sherwood Park, Tunbridge Wells.

FRENCH MEN OF SCIENCE IN BRITAIN

THREE weeks ago, we expressed the hope that some French scientific workers would succeed in reaching Great Britain. This hope has been realized and we are already in touch with some of them. At the time of the capitulation of their country, some were already in Great Britain ; some left southern France just in time ; others escaped, in more or less dramatic circumstances, from that part of their unhappy country now occupied by the enemy. At present, they are not a large body, but they hope, and we hope with them, that they may be joined by others who may follow in the future.

These French scientific workers have not come to Great Britain to seek refuge. They have come because they felt it was a duty to keep their place in the fight—in the fight that Great Britain is now facing alone ; they came because they still felt themselves tied to Great Britain by the solemn oath of France. They have been faithful both to their own ideals and to Great Britain. They have brought not only their readiness and their skill, but also information which will be of much service in Britain's war effort. General de Gaulle understood immediately the importance of this fact, and M. Labarthe has been appointed to take charge of the "Armaments and Scientific Research" Department of the French National Committee. So far as scientific research is concerned, the role of M. Labarthe's department will be to put the French men of science into touch with appropriate English laboratories, in order to ensure the best utilization of their skill in whatever branch of scientific or industrial research they are specially competent.

It is obvious that these French men of science cannot be allowed to enter laboratories where certain war research is going on, and we are sure that they themselves appreciate this fact. We hope, nevertheless, that they will not be prevented from joining the British war effort just because they are not British. They should certainly not be treated as enemy aliens ; indeed, the Government's offer of a month ago of complete union with France might be renewed in their case, and they might be allowed to obtain British nationality. at least for the duration of the War.

Some of the French men of science have special knowledge in branches which have no direct connexion with the war effort. They should find in the universities of Great Britain a friendly welcome, and the opportunity of continuing their researches in that atmosphere of freedom which is so necessary for creative scientific work.

Those who worked in France on war research are anxious to resume their labours in Great Britain. But they are fully aware that there may be little opportunity for long-distance research : they are ready to do any work in which they can be useful, even if it is in the nature of industrial routine ; and are prepared to take part in active defence measures in case of emergency.

The French scientific workers who have succeeded in reaching Great Britain are eager to help us in our war effort, and we must in our turn help them in every possible way. In the muddle and turmoil of the moral and military collapse of France, they have put aside all family and other ties, and have left their country in order to carry on the struggle for the ideals of democracy in which they believe. It would be but a small return for us to set them to work as soon as possible, so that they may be spared the anxious thoughts which must inevitably occupy their inactivity.

A PSYCHOLOGICAL 'HINGE' IN NATIONAL DEFENCE

JUST as German strategy concentrated on a weak hinge in the military defences of France, so in its general technique of invasion the German Command thrusts at what may be called a psychological hinge in the national defences : the weak point where military discipline ends and civil organization begins. Invasion by parachute troops co-operating with secret agents is the most dramatic form of the attack on this weak hinge. Its success in the neutral countries depended on military operations being carried out in an area which was still organized for civil life and looking to civil authority for direction. Military attack at that point in the national structure caused panic and confusion.

In Great Britain we hope that forewarned is forearmed. The question is, against what exactly have we been forewarned ? Against parachute invaders aided by secret agents ? But quite different tactics might be employed and yet fulfil the same military purpose through having the same fundamental effect psychologically.

This effect can perhaps be best described as a form of bewilderment. It results from the sudden shattering of deep-seated assumptions and expectations which the civilian—and possibly the soldier too—harbours about warfare. These assumptions are partly expressed in the formulated laws and usages of war. But the most important, psychologically, spring from less definite factors, such as custom, long-sanctioned sentiment, tradition ; or, in more modish guise, from the prevailing 'cultural patterns'. The German policy is to disrupt those patterns, and to take advantage of the resulting bewilderment.

One of our clearest cultural patterns—so long established as to seem 'natural'—is that of a strict differentiation of the military function within the community, with a specialized sub-group to perform it. Without this pattern there would be no foundation for the laws governing the treatment of non-combatants in warfare. This pattern has persisted up to the present time. Bombing from the air, it is true, brings civilians within range of military dangers and does something to blur the distinction between soldiers and others. Yet in its psychological effects the bombing we have experienced in Britain has been in some ways more like a natural calamity. It has been an ordeal in which the civilian has remained comparatively inert, passively enduring.

The psychological effect seems to be very different when the enemy's parachute troops are actually among civilians, carrying out a military attack against communications and transport in areas where ordinary civil life is the rule. If, in addition, low-flying aircraft deliberately machine-gun civilians in order to cause confusion, the sense of a personal attack is enhanced. Such attacks represent a much more intimate infiltration of military purposes into civilian life than aerial bombing has done in the past. The enemy is using his attack on civilians for a direct and immediate military purpose, that of hampering the army's operations by means of civil confusion.

Yet the civilians remain civilians. They have no training, no equipment, and no organization for resisting, and—what may be worse—they have no clear right even to resist by armed force.

The blurring of established social patterns is carried further in the use made by Germany of secret agents. The so-called 'Fifth Column' in the invaded countries has engaged not merely in espionage and sabotage, but also in actual military co-operation with enemy troops. Against these agents, presumably, even civilians would be entitled to use any force that they could. This seems to be implied in the official leaflet "If the Invader Comes", when it instructs factories to organize their own system of defence against sudden attack :

> "If you are in charge of a factory, store or other works, organise its defence at once. If you are a worker, make sure that you understand the system of defence that has been organised and know what part you have to play in it. Remember always that parachutists and fifth column men are powerless against any organised resistance. They can only succeed if they can create disorganisation. Make certain that no suspicious strangers enter your premises."

Examined carefully, the official wording here (and throughout the leaflet) can be seen to avoid giving sanction to armed action by civilians against parachute troops. The caution and vagueness of official pronouncement reflect the central difficulty : that of securing safety while still adhering to the usage of war in totally novel circumstances.

The Local Defence Volunteers represent the main attempt in Great Britain to meet this difficulty. They form the answer to a ruse which takes advantage of laws and customs that grew up in totally different circumstances from those created by the German strategem. The ban on the *franc-tireur* was based on the experience of armies of occupation which were in full military control of enemy territory. What were not envisaged were acts of brigandage by small bands of troops within territory the ordinary military defences of which are still intact. The enlistment of Local Defence Volunteers succeeds in maintaining the clear difference in military law between the soldier and the civilian, but it leavens the civilian population with men equipped for military functions and entitled to exercise military rights.

The fundamental answer to the German policy, however, has not yet been discovered. Full defence against the policy of social confusion can consist in nothing less than restoring psychological clarity to the situation. The secret agent was effective in countries where his own clear-cut intentions contrasted with the divided sympathies and faltering policy of those around him. In the Netherlands, it is reported, the 'Fifth Column' organizations were perfectly well known but were not proceeded against for fear of provoking Germany. In Britain, on the other hand, clarity of national intention should now be more easily achievable. Given that, police action, with the co-operation of the public, can handle the danger of the secret agent.

Against parachute invaders the precautions must in the main be military. Yet here the importance of the psychological 'hinge' can too easily be under-estimated and neglected. A civilian population untempered by military training and yet exposed to military attack presents a problem which has not yet been fully solved. The German politico-military Command has deliberately disrupted the older social patterns. Diplomatic pressure, military assault, brigandage, espionage, treachery, revolution, these are all familiar. But in the past they have been clearly distinguishable from each other. Now, however, the separate patterns have been dissolved and the new situation is a bewildering social hybrid. It remains bewildering so long as we try to grasp it in terms of the older patterns. In particular, the complete gulf between the civilians and the armed forces is an anachronism.

Up to the present, the policy of the army has been to work in the greatest possible isolation from civilian life. The civilian has been encouraged to cultivate total ignorance of the meaning of any military activity that cannot be entirely concealed from him. It should scarcely need technical psychology to make it clear that this policy will *not* prevent gossiping, rumour-mongering, and the spread of all manner of alarms and forebodings. Again, the policy towards civilians in a battle area has been the negative one of either evacuating them or of keeping them immobile and inert. But when battle areas are no longer neatly delimited, and new tactics make civilian panic much more likely, this policy is not certain of success. Moreover, it ignores the fact that the army may require much more positive co-operation from civilians.

The new circumstances make it dangerous for the army to persist in regarding civilians as nothing but an unavoidable nuisance. It would seem that the weak hinge between civil life and military organization must be strengthened. Much could certainly be done by the military authorities, without any leakage of vital information, to give the impression of taking the public into their confidence far more than they do at present. The leaflet "If the Invader Comes" makes it clear that the co-operation of the civilian public may be needed by the army authorities. Any more detailed expansion of the bare hints dropped by that leaflet would do something towards strengthening the weak hinge.

Many methods could undoubtedly be found of implementing such a policy if it were accepted in principle. There would be value even in so obvious a device as lectures to civilian audiences dealing in a general and non-committal way with the strategy and tactics which we may at any moment find ourselves involved in. Broadcasts have done a very little in this direction. In some ways, lectures given by military men in the actual presence of small civilian audiences would be more useful. They could have more local relevance. They would give more visible reality to the contact between civilians and military authorities.

The fact is that at present, to a great proportion of the civil population, a military officer on duty is psychologically foreign. This was of little account when wars were fought on a front line. In the new circumstances of war it is more serious. It represents a danger which can probably be met only by giving the civilian population a more visible, more local, and more definite role in their support of those who carry out the specialized military function.

SCIENCE IN ITS INFANCY

Science and the Classics
By Sir D'Arcy W. Thompson. (St. Andrews University Publications, No. 44.) Pp. viii + 264. (London: Oxford University Press, 1940.) 5s. net.

THIS dainty little book, elegantly produced by the Oxford University Press, does not pretend to be a history of science in classical times. Sir D'Arcy Thompson did not but collect in it twelve lectures delivered by him on different occasions from 1910 until 1935 (a distinguished jubilee), and connected with various aspects of science, as it was conceived and understood in this remote period, when the foundations of science were laid.

Sir D'Arcy Thompson, after winning a well-earned holiday from a laborious and long scientific and scholarly life, remembered the Greek motto which he quotes:

ἅ δ' ἄν μάθη τις ταῦτα, σῴζεσθαι φιλεῖ πρὸς γῆρας

and which he interprets in his own felicitous manner, by saying:

> "Science and the Classics! The one says (in Wisdom's words): They that eat of me shall yet be hungry. And the other says: They that drink of me shall yet be thirsty. And both alike continually enlarge our curiosity, and multiply our inlets to happiness."

Nevertheless, this book, composed in a restrained scope and scattered form, by a man to whom I should like to apply the Sophoclean verse:

φῦναι τὸν ἄνδρα πάν' ἐπιστήμης πλέων ·
(The man being full of knowledge)

constitutes a valuable contribution to the theme.

We are accustomed to look to classisism and its productions, not so much for scientific speculations and achievements, as for the highest pleasure of intellect, triumphs in expression of the human mind, or the enjoyment of impeccable forms, all attained sometimes, but never surpassed, by moderns.

Sir D'Arcy, however, teaches us that many of the classics we love and admire were interested in purely scientific speculations. As he puts it admirably: "It has been the rule from time immemorial, not the exception, for science and the humanities to go hand in hand. Aristotle the naturalist wrote of poetry; Plato was a lover of astronomy; Theophrastus the botanist was a master of rhetoric, whom even Cicero admired; Celsus the physician was an encyclopædic scholar after the taste and fashion of his age. When the humanistic tradition was at its height in the 'revival of learning', Galen and Hippocrates were read by all". May I add that Ptolemæus, the great man of science of the second century A.D., who founded the Ptolemaic system and was a writer on astronomy, chronology, geography, and music, in the elation for his work as an astronomer, composed the well-known epigram in which he compares himself, for exultation and pleasure, to a god—no less than Jupiter. This epigram, which I expected in vain to find quoted in Sir D'Arcy's chapter entitled, "Astronomy and the Classics", runs as follows in the translation of F. L. Lucas:

> "I know well I am mortal, a feeble thing and fleeting;
> Yet when I watch the wheelings of myriad star on star,
> My feet touch earth no longer. It is as I were eating,
> At the high God's own table, of Heaven's ambrosia."

Sir D'Arcy, following the examples he mentions, combines the status of a distinguished naturalist with that of a prominent classical scholar, and it is to this happy combination to which we owe first his great work, "The Glossary of Greek Birds", and now the present little volume of "Analecta", a fruitful wandering among the flower-beds of classical gardens and the more austere alleys of scientific speculations.

The chapter, "Aristotle the Naturalist", he compiled with a special interest, as this great Greek, being a philosopher and a writer on the most various of subjects, also distinguished himself as a naturalist, and thus it may be said that Sir D'Arcy has in some ways claims analogous to those of Aristotle.

I find in this chapter, with an understandable pleasure, the confirmation of what I tried to explain in regard to the description of Nature in Greek poetry, when reviewing lately, in these columns, Dr. Soutar's book (NATURE, April 27). It is so much more strikingly expressed by Schiller, whom Sir D'Arcy quotes, that I cannot but yield to the temptation of transcribing herewith the passage:

> "As Schiller puts it, the Greeks looked on Nature with their minds more than with their hearts, nor ever clung to her with outspoken admiration and affection; and Humboldt, ascerting (as I would do) that the portrayal of

> Nature for her own sake and in all her manifold diversity was foreign to the Greek idea, declares that the landscape is always the mere background of their picture, while their foreground is filled with the affairs and actions and thoughts of men. But all the while, as in some old Italian picture—of Domenichino or Albani or Leonardo himself—the subordinated background is delicately traced and exquisitely beautiful; and sometimes we come to value it in the end more than all the rest of the composition."

Sir D'Arcy has a system of his own, which he seems to recommend to others—although those who may follow his example must have the extent of his interest in reading and taste for choice. He takes note-books, he labels them according to a specified subject, and fills them with quotations, remarks and thoughts. To one of these note-books we owe the charming chapter under the title: "Games and Playthings". Sports and toys seem to have but a remote relation with science. Nevertheless, games have their science, and toys, even in those times to which Sir D'Arcy refers, have sometimes a scientific character. Playthings in the nursery of the classical period may have some similarity to those used by children of the present age. The *Krotalos* is merely our rattle. *Nymphæ*, *Koræ* and *Plangones* are simply the dolls of our girls. There is, too, the *Platagonion*, but this is not a toy. It is a custom, combined with a superstition, which curiously enough is still preserved in modern Greece. The word designates the broad leaf of the poppy, and ancient Greeks used to lay it on the palm of their hands and strike it smartly on the foreheads; it was a good omen if it burst with a loud crack. The *Roptron* is our tambourine—and so on. But we do not possess any toy similar to the extraordinary *psiphoperimombitria*. The actual game for the children was to pronounce the polysyllabic word rather than to play the toy.

The most scientific and fascinating chapter in the book is the lecture the author gave in the year 1921 at the University of Brussels in an elegantly perfect French, which would do credit to any French stylist. He developed in it the theory of *logarithmic spiral*, so strikingly demonstrated in the construction of the shell of the nautilus and other shell-fish as well as in the marvellous spider's cobweb, one of the wonders of Nature, for its unfailing geometrical perfection and unsurpassed delicacy of its thread. It is of the surmised logarithmic spiral that Pythagoras was thinking when he proclaimed the axiom: θεὸς αἰεὶ γεωμειρεῖ which Sir D'Arcy renders into French as: "Le bon Dieu fait toujours de la géometrie". But is the magnificent Greek phrase translatable?

The lectures contained in the volume do not deal with mechanics in classical times. If not a classical, but a mythological legend, that of Icarus made me always guess dreamily of it. Is the single flight of the handsome youth and his fatal fall a mere poetical phantasy or does it correspond to some reality, from which the legend spurted? Or by what mechanical means exactly the enormous blocks of marble from the Pentelicum were transported to the steep hill of the Acropolis for building there the immortal temples still standing erect, though cruelly injured by time, weather and barbarians? I wonder if there will be ever a definite answer to such queries.

Specialists or mathematically minded readers will read with pleasure and profit the two chapters: "Plato's Theory of the Planets" and "Excess and Defect: or the little more and the little less". Moreover, the volume itself will find a choice place, for consultation and relaxation, on the appropriate shelf of the library of the lover of classics.

Demetrius Caclamanos.

ELECTRICAL ENGINEERING MATHEMATICS

Mathematics Applied to Electrical Engineering
By A. G. Warren. (Monographs on Electrical Engineering, Vol. 9.) Pp. xv+384. (London: Chapman and Hall, Ltd., 1939.) 15*s*. net.

An editorial preface by Mr. H. P. Young, an appreciative foreword by Dr. Alexander Russell, the usual author's preface, four chapters of elementary 'pure' mathematics (complex numbers and calculus), a concise statement of the mathematical relationships of electricity and magnetism in a single comprehensive chapter, and the book may be considered to be about to commence. In Chapters vi and vii we have many diverse 'applications'. But in Chapters viii and ix we have more 'pure' mathematics—more advanced (partial differential) equations and more advanced methods of integration—in fact, with the exception of a few examples in Chapter x, the whole of Chapters viii–xii can be described as pure mathematics. But in Chapters xiii and xiv we have some real practical problems.

Back to pure mathematics—still more advanced—in Chapters xv, xvi and xvii, and finally some special problems for the remaining four chapters; thus, electromagnetic waves in space and along wires, Fourier's series and harmonic analysis, Heaviside's operational calculus, and conjugate functions.

"A text-book of mathematics with some examples in the field of the electrical (mainly communications) engineer" would perhaps be a more descriptive title. The reviewer is not a mathematician and certainly not qualified to review a mathematics text-book; but as a communications engineer he can say that in this book he has found all the mathematics that he has ever had to use and much that he has always wanted to be able to use. If there is any criticism to be made, it is that there should be a greater subordination of the mathematics to the physics of the problem. Equations are stated as describing the phenomenon, the mathematical handle is turned, and the solution emerges. But the fundamental problem of the formulation of the mathematical expressions in connexion with the physical problem, which is necessary before the equations can be arrived at, is perhaps not given sufficient attention. This, to the mind of the reviewer, is the real 'application' of mathematics.

The average engineer has a pocket-book of formulæ, and his one problem is to choose the right formula. Is he much worse off than the engineer who has a book of equations—the appropriate one of which he must choose—but who has learned to turn the mathematical handle and get his own solution or formula? But the engineer who from a study of the physics of his problem can think in such a way that he can write down his own equations and then solve them (or get a mathematical friend to do so) is definitely of a different standing.

The book will find a prominent place on the reviewer's bookshelf, and he will expect to refer to it frequently.

ELEMENTARY GEOMETRY

Elementary Mathematics from an Advanced Standpoint

Geometry. By Felix Klein. Translated from the third German edition by E. R. Hedrick and Prof. C. A. Noble. Pp. ix + 214. (London: Macmillan and Co., Ltd., 1939.) 15*s*. net.

THIS book continues the translation of Klein's "Elementar Mathematik" which Messrs. Hedrick and Noble began with their translation of the volume on arithmetic, algebra, and analysis. The volume under review is that devoted to geometry. It cannot be claimed that the translation is perfect; some sentences are English only in the sense that English words are used, but in construction they are essentially German, and there are some eccentricities in spelling, for example, "parellelopiped". There are also some slips which may irritate the reader: for example, on p. 180 a footnote reads, "In the *Sixth Memoir on Quantities* [*sic*], already cited (p. 145)," and it appears that the reference is to Cayley's memoir on quantics which is correctly quoted on p. 134, not p. 145.

But in spite of these imperfections, the translators have done a useful piece of work in making Klein's volume available to teachers of mathematics who are unable to read the original German text. Klein's comprehensive treatment of the classical geometries and his exposition of the relationships between them have done much to clear up the muddle in which geometry was in danger of being lost, and it is very important that as many as possible should have the opportunity of studying the views of such an eminent mathematician on matters which concern every teacher of mathematics. It can be said that the translators have faithfully communicated the point of view and the general spirit of the original text.

It has often been said, of course, that Klein's definition of geometry is old-fashioned, and does not cover all that present-day mathematicians know as geometry. If this is true, one may ask whether Klein's work has not outlived its usefulness, and whether there is any justification for translating it at this date. We think that there can be no doubt about the answer: Klein's work has still great value, and every teacher of mathematics should be acquainted with it.

In what ways do Klein's ideas fall short of modern requirements? There are two respects in which geometry has outgrown the views expressed in this book. In the first place, there is more than one branch of mathematical science which is now commonly regarded as a geometry, and which cannot be regarded as the theory of invariants of a group of transformations in the sense meant by Klein. This point has been discussed in several places (see, for example, Veblen and Whitehead's Cambridge Mathematical Tract, No. 29, p. 31). But we do not think this in any way puts the book out of date. Klein's whole idea is to show teachers of mathematics the interrelations of the various geometries which their pupils will have to study in schools and during the earlier stages of their university careers, and for this purpose the point of view of the Erlanger Programm is not merely adequate, but the best. The pupil will want to extend his ideas of geometry at a later stage; but this should be left until he gets into the hands of the geometry specialist.

The other direction in which geometrical thought has developed beyond the limits of the Erlanger Programm is in the conception of the space in which the transformations are effected, even in the case when we do not go beyond projective geometry. Klein begins his survey from the study of ordinary (real) Euclidean geometry, then introduces the "improper elements"—elements at infinity, imaginary points, and so on. So he goes on until he reaches the conception of the geometries under consideration as the invariant theories of groups of transformations in his generalized space, the projective group containing the others as sub-groups. Then, in the last part of the book he considers the foundations of geometry, starting with the propositions of incidence. It is at this point that we feel that Klein would, if he were writing to-day, modify his work most extensively. By using the ideas of continuity, order, etc., he limits the space with which he is concerned until it is, effectively, the projective space in which the co-ordinates are ordinary numbers, complex if we make use of von Staudt's theory of imaginaries. But, how much of what is involved in this is really required? It is known that if a projective space is defined by means of the propositions of incidence and Pappus' theorem, we can introduce co-ordinates which are elements of a uniquely defined algebraic field, and this gives us nearly all that we want. It is true that in elementary geometry it is usually assumed that the field is of characteristic zero and is algebraically closed. The first condition is easily stated in geometrical form; with regard to the second, it would probably be enough in an elementary account to state as an additional defining condition that the field is algebraically closed, giving examples to show what this implies. We believe that Klein, who repeatedly expresses the desirability of connecting geometry with other branches of mathematics, might well have favoured this modern algebraic method of laying the foundations of geometry, and by his genius have provided the best possible exposition of it.

CROP HUSBANDRY

An Outline of British Crop Husbandry

By Dr. H. G. Sanders. Pp. viii + 348 + 6 plates. (Cambridge: At the University Press, 1939.) 15*s.* net.

THIS is a book which all agricultural students will find instructive. It is set out in a form which can be understood by everybody possessing an elementary knowledge of agriculture, and the enumeration of the reasons and advantages of the methods of procedure discussed will help the student to memorize them. The student will also find the bibliography at the end of each chapter extremely useful. The author has not merely given a list of books of reference, but also mentions papers from journals dealing with the subject. Only an author well acquainted with current literature could have covered so large a field.

Practical farmers will think that the book rather smacks of the lecture room, but they will find it interesting in that their attention is directed to the reasons underlying the various operations that they know from experience are advantageous. The chapter dealing with the choice and treatment of seed should be of interest to them, for at present insufficient attention is given to these important points.

Certain chapters of the book are rather unnecessarily long, and contain too many examples of rotations and dates of cultivation; in practice, rotations are usually broken, and dates of cultivations depend to a large extent upon uncontrollable factors. Evidence is also beginning to accumulate which at present tends to show that perhaps time and money is being wasted by over-cultivating the land.

The chapters on manuring and cleaning the ground will be useful to farmers. The general effects of the different kinds of manures are well set out, with an indication of the type of manure most suitable for the different crops. Fortunately, tables giving results of experiments are not included. The principles underlying the various operations on a fallow are explained; if these were more widely known to farmers, we should not see so many green fallows as we do.

The latter part of the book deals largely with matters about which the modern farmer has little to learn, but which are extremely useful to the agricultural student.

On the whole, it is an interesting and useful book, which will be of far more use to the student than the farmer, though all practical men would learn something from it. J. R. M.

Where is the —— Collection?

An Account of the various Natural History Collections which have come under the notice of the Compiler, Dr. Charles Davies Sherborn, between 1880 and 1939. Pp. 150. (Cambridge: At the University Press, 1940.) 3*s*. 6*d*. net.

THE difficulty of discovering the resting place of some important specimen has been encountered by most systematists, and doubtless justifies the "blue-pencilled" word which the author may or may not have hinted at in the title of this little book. Here about 1,700 entries give names of persons the fate of whose collections is briefly indicated.

Clearly it is impossible in the first instance to make such a catalogue complete; even important collections like the "Discovery" collections in the British Museum or the "Scotia" collections in the Royal Scottish Museum or any of the great Antarctic collections, and many others, are not mentioned. But it is misleading when entries are incomplete or inaccurate: "Edinburgh", "Edinburgh Mus.", "Edin. Mus. Sci. and Art", all inadequately indicate the Royal Scottish Museum, and in it are preserved Hugh Miller's collections and not "in his home at Cromarty"; the famous Dufrêsne collection was bought in Paris by the University of Edinburgh in 1819 for £3,000 and such of it as remains, including some type specimens (not "shells" only), is also in the Royal Scottish Museum; the collections of Sir Charles Lyell, rocks, minerals and fossils, are not "at Kinnordy", but in the Department of Geology of the University of Edinburgh. These and similar deficiencies can be put right in time; the chief concern is that Dr. Sherborn's vast knowledge and painstaking labour have created a foundation upon which a complete *Catalogus Thesaurorum* may be erected, and which in the meantime will be invaluable for reference.

JAMES RITCHIE.

Physiology in Health and Disease

By Prof. Carl J. Wiggers. Third edition, thoroughly revised. Pp. 1144. (London: Henry Kimpton, 1939.) 42*s*. net.

THE appearance of a third edition of one of the major American text-books of physiology will be welcomed by teachers of physiology. Extensive revision includes the addition of 1,400 new references, and it is as a guide to the recent literature that the book is likely to make its strongest appeal. In sections in which the emphasis on recent developments is most marked, the impression of a collection of stop-press news sometimes disturbs that of a well-digested presentation. In the course of the transfer from the summaries of original papers to the text, condensation has in some instances played havoc with the sense of the matter described, and a rather high measure of verbal carelessness enhances the feeling that the book does not represent quite the unhurried and matured conception of physiology for which we would have hoped from so distinguished an authority.

The illustrations are not very plentiful and many of them are not very telling. Ingenious and elaborate schematic diagrams of physiological processes and their relations abound, and will satisfy the craving for such things of the most enthusiastic examinee. Nevertheless, the book is alive and has quality, and will continue to be valued as one of the larger standard text-books by lecturers and advanced students of physiology who are concerned with those parts of the subject required for an understanding of human disease.

Earth Science

A Physiography. By Gustav L. Fletcher. Based on "New Physiography", by Albert L. Arey, Frank L. Bryant, William W. Clendenin, William T. Morrey. Pp. v+568. (Boston, New York and Chicago: D. C. Heath and Co.; London: George G. Harrap and Co., Ltd., 1938.) 7*s*. 6*d*.

THE text of this book is based upon Arey, Bryant, Clendenin and Morrey's "New Physiography"; but the order of topics has been entirely rearranged and the subject-matter completely rewritten. As an introduction a general account of the past history of the earth is given, followed by a description of the dynamic forces that are changing the face of the earth to-day, and a study of the material composition of the earth. For the sake of familiarity the land is first surveyed, the author then proceeding to describe the earth's relations in space, the seasons, latitude, longitude, the atmosphere and associated phenomena like weather and climate. The book is rounded off with a study of the sea, special emphasis being placed on harbours. An interesting feature is the inclusion of a completion summary at the end of each chapter. This the reader is required to copy and complete; it is intended to counteract the bad practice of reading only the summaries of chapters. Each section is provided with a range of questions involving every important point raised in the text. The diagrams are clear and liberally distributed, the majority of them being illustrative of North American earth formations.

Protozoology

By Prof. Richard Roksabro Kudo. Enlarged and completely rewritten edition of a "Handbook of Protozoology". Pp. xi+689. (London: Baillière, Tindall and Cox, 1939.) 36*s*.

IN this edition the author has largely rewritten his text, and has also expanded the book to include certain subjects which were not touched upon in the earlier edition. The sections on morphology and physiology have been extended, though the latter appears to deal largely with work published before the first edition of this book was issued. Two entirely new chapters are devoted to ecology, and to variation and heredity. Although the soil is mentioned as an environment, no suggestion is given of the richness of its fauna, nor are some of the common soil species attributed to this habitat. In the taxonomic section a large number of species has been added, though it is still possible to find omissions; but perhaps this is to be expected in a work of this size. More than one hundred new illustrations have been included, and an adequate bibliography is supplied to each chapter.

AN AZTEC HERBAL

By DR. AGNES ARBER

OUR fragmentary knowledge of the early history of botany in Mexico has lately received a remarkable addition in the form of a reproduction of a manuscript herbal of the sixteenth century, written by an Aztec physician, and now edited by Dr. Emily Walcott Emmart[1]. It had long been known that, by the period of the Spanish conquest, gardening and medicinal botany in Mexico had reached a high degree of elaboration[2]. The fact that the language of the Nahuas included several different names for different types of garden, shows that horticulture played a considerable part in their lives. Montezuma possessed gardens for flowers and medicinal herbs, in which, according to the chronicler, Cervantes de Salazar, he "did not allow any vegetables or fruit to be grown, saying that it was not kingly to cultivate plants for utility or profit in his pleasance". He also owned vegetable gardens and orchards, but these he seldom visited, since he held them to be "for slaves or merchants". His contempt for mere utility did not extend, however, to curative herbs. He ordered his physicians to make experiments with the medicinal plants in his gardens, and to use the best-tried remedies for the benefit of the lords of his court.

Montezuma the Elder, in the fifteenth century, restored an ancestral tropical garden at Huaxtepec. It is recorded that he sent to the Lord of Cuetlaxtla for plants with roots of the vanilla orchid, cacao, magnolia, and other exotics, and asked that they should be escorted by native gardeners capable of cultivating them. His directions were followed religiously, and the plants arrived with their roots in earth and wrapped in beautifully woven mantles. The gardeners, before replanting these treasures, fasted for eight days, and made sacrifices of incense and other offerings before the god of flowers. This procedure was a great success: the plants flourished exceedingly, and Montezuma wept with joy at the triumphant result of the experiment. Dr. Zelia Nuttall, in whose work a fuller account of these matters will be found, writes that nothing now remains of this—the first tropical botanic garden of the American continent—except a few immemorial cypresses.

In 1570 a certain Francisco Hernández was sent to Mexico by Philip II to investigate the natural history of New Spain; he was the first European botanist to study the vegetation of the New World. He spent seven years in Mexico, passing much of his time in the garden of Huaxtepec. It was not until the middle of the seventeenth century, however, that his great work upon the plants of Mexico saw the light; but at an earlier date (1615) Francisco Ximenez issued a partial Spanish translation of it, which has the distinction of being the first published book treating of the herbal remedies of the Aztecs. It has now, however, yielded pride of place, as the first record of the subject, to a small Latin manuscript, bound in crimson velvet of the sixteenth century, discovered in 1929 by Prof. Charles U. Clark in the Vatican Library; this work proved to be an Aztec herbal in Latin, with pictures. In the same year an Italian translation of the Vatican manuscript was found in the Royal Library at Windsor. The Vatican copy has been studied in extreme detail by Dr. Emmart, who, with the aid of a number of public and private benefactors, has been able to publish a coloured and copiously annotated facsimile of the herbal. The whole work is on a sumptuous scale, though the price has been kept intentionally to a low level, in order to bring it within the reach of students.

Soon after the Spaniards had conquered Mexico, schools for the Indians were built with funds provided by the treasury of Charles V. In the Convent of San Francisco in Mexico City, native boys were taught reading, writing, music, and other subjects. These pupils were found to be so teachable that a further step was taken in 1536, when the College of Santa Cruz was established at the Convent of Santiago on the outskirts of the same city. Here the students learned Latin, philosophy, logic, arithmetic, and music. Moreover, the Spaniards realized so fully the importance of the indigenous pharmacopœia, that they brought to the College the best known of the Indian physicians, so that they might hand on the knowledge of native herbs. It was one of these teachers, Martinus de la Cruz, who compiled the recently discovered herbal; its translation into Latin was due to Juannes Badianus, an Indian who was "Reader of Latin" in the College. The manuscript is modestly described on the fly-leaf as "A little book of Indian medicinal herbs, composed by a certain Indian, physician of the College of Santa Cruz, who has no theoretical learning, but is thoroughly instructed by experience alone. In the year of Our Lord Saviour 1552". The work was undertaken as a gift for Charles V, at the request of Don Francisco de Mendoza, to whom it was dedicated. Its intention was primarily medical;

the plants are grouped under the diseases which they are reputed to cure.

Pliny's "Natural History" was one of the Latin texts used by the students of the College, and the latinity of Badianus is said to show signs of Pliny's influence. Since, however, the plants are not those of Europe, they are kept under their Aztec names, which are spelt phonetically and not latinized. Apart from its interest for the history of medicine, the most striking feature of the book is the beauty of the illustrations, which approach two hundred in number. Dr. Emmart concludes that they were probably the handiwork of Martinus rather than of Badianus, but they show so much accomplishment that it may perhaps be suggested that they were executed neither by Badianus, the classical lecturer, nor by Martinus, the physician, but by some professional artist whose name has not come down to us. The peculiarly rich colour of these pictures contrasts happily with the warm tint of the paper, the crimson lettering used for the plant names, and the reddish-orange marginal lines, which enclose the pages. Mexico in early days was famous for its brilliant native dyes, and Cortez wrote that paints of good quality could be bought in the market-place of Tlaltelolco.

To those accustomed to European botanical illustrations, the way in which the roots are portrayed is the most unfamiliar feature of the figures in the Badianus herbal. The technique is difficult to describe in words ; but it may be said in general that the root system is indicated in a conventional fashion on a patch of background varying in colour and form. Sometimes the Aztec stone- or water-symbol can be detected. Dr. Emmart claims that in the treatment of the roots, "there is an attempt to represent the ecology of the plant pictorially—a direct carrying over of Aztec pictographic representation". A comparison of the roots throughout the herbal offers—at least to the uninitiated—no very obvious confirmation of this view ; if such symbolism was intended, it is, except in special cases, curiously variable and obscure. It is perhaps possible that an explanation of a slightly different and more prosaic type may be worth considering. In Mexico "chinampas", sometimes erroneously called "floating gardens", have been used from antiquity and may still be seen to-day (Nuttall). They are raised mud beds, artificially built up in lakes or lagoons, staked off with cane, and bordered by pruned willows, the interlacing roots of which are trained to form a sort of basket-work which holds the banks. A special method is used for the transplantation of young annuals from mud beds in which the seedlings have been set out. The substratum is cut up deftly into solid blocks, and each plant is lifted with a compact mass of soil enclosing its roots. If the Aztec artist who illustrated the Badianus herbal was accustomed to this mode of handling plants, it might seem natural to him to represent roots in association with a block of the substratum. It is noticeable that, when very small plants of a mossy or turf-like habit are depicted, the individual plant with its roots is not isolated, but a whole group is shown, growing on what is apparently a block of soil. Later research may perhaps prove that the colouring and decoration of these blocks and balls of soil had a well-defined symbolic meaning, but, judging merely from appearances, it looks as if the artist had just enjoyed himself in giving free rein to his painter's fancy.

As representations, the illustrations of the Badianus herbal are of very unequal merit : among the best are those of an aroid (Xanthosoma); two species of Datura ; a species of Commelina ; and two cacti (Opuntia and Cereus). A great many of the pictures are, however, quite unrecognizable, and bring to mind European herbal illustrations in the degraded condition which they reached after a process of copying from manuscript to manuscript which extended over centuries. Indeed, in looking through the Badianus herbal, one cannot but be struck by the fact that both the realistic and the more conventionalized examples show a decided resemblance to Old World herbal drawings of the period before printing. The general style often so closely recalls that of European plant pictures, that it is difficult to believe that the Mexican figures owe nothing to the stream of artistic tradition which can be traced back to Greek botanical illustration dating from before the beginning of the Christian era.

The American scholars concerned with the Badianus herbal take, however, a somewhat different view. Dr. Sigerist, who writes the foreword, says that the manuscript is "a purely Mexican product", and that "as far as we can see, it shows no traces of European influence". Dr. Emmart also takes the view that "whether the authors of the manuscript ever saw and studied an illustrated European herbal, is a question of considerable doubt", and she regards the technical skill of the Aztec illustrator as "indigenous to the soil of Mexico and not obtained by contact with European culture". No one would, of course, wish to deny that these illustrations are, to a great extent, the outcome of a long tradition of Mexican art ; we know, for example, that Nezahualcoyotl, the fifteenth-century king of Texcoco in the valley of Mexico, had pictures of tropical plants painted from Nature and copied on to the walls of his palace. Nevertheless, we may be allowed to feel that the native tradition was to some extent overlaid, in the Badianus herbal, by European influences ; otherwise we have to postulate a degree of parallelism exceeding probability, between the highly stylized and sophisticated schools of herbal illustration of the Old and the New Worlds.

It should be remembered that the Indians were highly susceptible to the education offered to them by the Spaniards; in the year 1541, Gerónimo López wrote that some of the Indian boys "speak Latin as elegantly as Cicero". We are told, also, that in the Convent of San Francisco, those native boys who showed ability in drawing and writing, were given the task of illuminating manuscripts; here influences from Europe had a direct opportunity of playing upon Aztec art. The staff of the College of Santa Cruz must have consisted of men of broad culture, and they cannot have carried on their work without books. Even though they were sojourning in a country with an unfamiliar flora, it is unlikely that illustrated herbals found no place in their library, considering the importance then attached to these books from a medical point of view. We may at least conclude that the possibility of European influences having had their role in determining the style of the pictures in the Badianus herbal, cannot at present be rejected. It is to be hoped that the later work of American students of the Aztec civilization may reveal more decisive evidence on this point.

The Badianus herbal contains an important body of directions for the treatment of ill-health, not only by pharmaceutical, but sometimes also by surgical methods. Occasionally there are indications of a surprisingly enlightened attitude. For example, both melancholia and fatigue are recognized as conditions for which medical treatment is suitable. The needs of the ancient Aztecs are indeed ours to-day, for we read of certain medicaments intended to relieve the "fatigue of those administering the government and holding public office", and also serving to "drive weariness far away, and, finally, to expel fear, and fortify the heart of man".

TREATMENT OF HOUSEHOLD REFUSE

By W. Carmichael,
Lighting and Cleansing Department, Edinburgh

THE first question asked by a local authority before embarking upon expenditure in connexion with an intensified salvage campaign is: How much salvage should we extract from our refuse? This is followed by the query as to the value of the expected salvage, and then: What is the position of the markets for the materials so extracted?

The second question is most easily answered by local rather than national inquiry, but the first question may be partly answered by the experience of other towns, although it is not possible to lay down a hard-and-fast table of quantities per ton of refuse which may be expected throughout the whole of Great Britain. The average percentages of the seasonal analyses of household refuse conducted under the ægis of the Ministry of Health, prior to the War, offer a guide; but, as the War has had an effect on normal ways of living, it is prudent to expect this effect to become noticeable in the constituents of the household refuse. Accordingly, the pre-War analyses only comprise a stop-gap until local authorities can institute analyses of their own. The results already achieved by many towns may appear very gratifying from a cash or gross tonnage point of view; but actual analyses of refuse should be carried out in order to be sure that the full salvage value is being realized.

Few towns are achieving the expected percentage of waste paper expected, namely, one ton per 1,000 of the population per month, or, expressed approximately in terms of refuse, 4 per cent of paper of the total tonnage of refuse handled. Despite the curtailment in the output of paper, this percentage of paper at least is, I am certain, available in every town in Great Britain. In making this statement, I am not taking Edinburgh's high figure for waste paper and making it applicable to all. For the week ending June 8, the percentage of waste paper to total household refuse collected in Edinburgh was 10 per cent. For the month of May, the total sales of waste paper collected by Edinburgh Cleansing Department amounted to 682 tons 6 cwt., with a revenue of £2,809; this tonnage represented 8·6 per cent of the total household refuse collected during the month. The high percentage of paper to refuse in the week ending June 8 was due to a sudden spell of hot weather which caused a drop in the ash element of the refuse. These figures show that a collection of one ton of waste paper per thousand of the population per month is quite possible. The annual recovery of waste paper throughout Great Britain at this rate would represent more than half a million tons. This would be fully one hundred per cent increase on the present rate of collection, and, moreover, sufficient to satisfy the needs of the paper- and board-making industry.

There should be no need to emphasize that the collection of waste paper will prove economical to the collecting authority. A glance at Paper Control Order No. 15 will convince. Present prices for waste paper, loose and baled, are :

	Loose	Baled in 4-ton lots
Newspapers	90*s*. per ton	127*s*. 6*d*. per ton
Strawboards ..	65*s*. per ton	105*s*. per ton.
Books and magazines	70*s*. per ton	107*s*. 6*d*. per ton
Mixed paper ..	40*s*. per ton	80*s*. per ton

In Edinburgh, the revenue from paper pays for the wages of all operatives on refuse disposal and paper collection and sorting, and leaves a surplus.

Prior to the War, Edinburgh could expect 1¼ per cent of household refuse to comprise rags. When an analysis was taken recently, we were surprised to find that the percentage of rags was equally as high as that of the pre-September period. However, it is too optimistic to look for such a figure to-day and we prefer to base our output on the Ministry of Supply's expectations, namely, 2 cwt. per thousand houses weekly. There are 120,000 households in Edinburgh, and our total of rags for the week ending June 8 was 11 tons, or just under the Ministry of Supply's expectations. Rags output per household may not be considered so constant as that of paper and its fluctuations will depend more upon economic considerations than does paper, the use of which is more temporary and output dependent on control.

Bones are expected by the Ministry of Supply on the basis of 1 cwt. of the population per month, but, obviously, this figure cannot be expected throughout the whole year. Warm weather is accompanied by a smaller consumption of butcher's meat than cold weather and, accordingly, the summer output might be put at ½–¾ cwt. per 1,000 of the population per month. At present, Edinburgh has been responsible for a little more than half the total of all bones collected in Scotland. The success achieved in the collection of this very important item of salvage has been due in no small measure to the adoption by the Edinburgh Education Committee of the scheme to collect bones through the schools. This scheme was put into force in February and bins were supplied to ninety-five schools for the reception of the bones wrapped in paper. The Medical Officer of Health gave the scheme his blessing from the start, which factor anticipated and effectively answered critics of the scheme from a health point of view.

Probably the householders' response to the appeal for salvage will be greatest in the realm of ferrous metals. Here again, however, tonnage will be a passing phase and, after a thorough comb-out of substantial items, authorities will fall back upon the humble tin can for their constant source of scrap.

Edinburgh has the credit of being one of the leading towns in Britain for salvage consistency and, accordingly, its methods of salvage may be of interest to other towns.

From the salvage point of view, the completion of Edinburgh's new disposal plant at Seafield in the month of the outbreak of war, and its commencement on September 21, came at a most fortunate time, as it meant that, thereafter, the total output of Edinburgh's household refuse would be mechanically treated in plants which offered the opportunity for maximum salvage extraction. The Seafield plant has a capacity of 140 tons per day ; Russell Road (opened in March 1938), 240 tons per day ; and Powderhall, 200 tons per day.

The efficiency of Edinburgh's disposal plants in the extraction of salvage can be illustrated by an analysis of the extraction at Russell Road for the week ending June 15 :

TOTAL REFUSE TREATED : 684 TONS 10 CWTS.

Salvage extracted	Tons	Cwt.	Percentage of refuse
Metals	44	5	6·45
Bottles (8,040) ..	3	7	0·49
Rags	10	19	1·60
Paper	45	13	6·67
Bones	—	15	0·12
Cullet	2	11	0·37
Cinders	70	—	10·20
	177	10	25·90

Thus it appears that 25 per cent of household refuse can be sold for re-use. If the experiments presently being carried out on the city's farms to test the fertilizing properties of the 50 per cent of dust now being screened from the refuse are as successful as the initial reports suggest, it may well be that, in the near future, Edinburgh will be re-selling 75 per cent of the total household refuse collected.

During the week referred to above, in addition to 84 tons of waste paper recovered at the disposal plants, 80 tons were collected by the special collection service. This service, which has been operating since before the War of 1914–18, has collected in the aggregate since that time 51,551 tons of waste paper, which have been sold for £93,126. The service has gradually increased from two horse lorries to ten. Each lorry has a specified route each day, and is entirely devoted to the collection of waste paper. Sacks are supplied to all households or business premises which will take them, and they are collected at weekly or fortnightly intervals. Some 20,000 sacks are in circulation.

The instructions given to Edinburgh householders for the preservation of their re-usable waste, so that the City's Cleansing Department may have it in its best condition, are simple. They are asked to put aside paper and rags to avoid contamination by contact with ashes, etc. Bones should be sent to the school bin ; or they can be put in the ash bin and they are then extracted from the refuse at the disposal plants. Collecting vehicles removing refuse carry sacks for the removal of paper and rags.

Recently a salvage shop was opened and, in the space of four weeks, it had attracted 100,000 visitors. In the first week, fifty requests a day were received for the special removal of accumulations of salvage; but, in the succeeding weeks, the number of requests went up to 100 per day. Hourly talks on salvage were given by loudspeakers and, in addition, there was a cinema room where a salvage film, running for ten minutes, was shown at half-hourly intervals throughout the day. This exhibition, without a doubt, has done much to make Edinburgh citizens more "salvage-conscious" than hitherto.

A FRENCH EXPEDITION TO THE CAMEROON MOUNTAINS

By RENAUD PAULIAN,
MUSÉUM NATIONAL D'HISTOIRE NATURELLE, PARIS

IN the summer of 1939 the Muséum National d'Histoire Naturelle de Paris, the Comité de la France d'Outre Mer du Centre National de la Recherche Scientifique, and the International Institute of Volcanology, in full accord with the British Museum (Natural History), sent a scientific expedition to the volcanic mountains of the Cameroons. This expedition consisted of B. Gèze, geologist, P. Lepesme, entomologist, A. Villers, assistant taxidermist, and myself, entomologist. We were to study the biological conditions prevailing on the principal mountains of the Cameroonian range, and we visited Mt. Cameroon (4,070 m.), Mt. N'Lonako (1,800 m.), Mt. Manengouba (2,400 m.), and Mt. Bambouto (2,600 m.). From a climatic point of view, it appears that the rainfall decreases regularly from more than 10 m. a year to about 2 m. a year from the first to the last of the above-named mountains. Together with this decrease in rainfall, human settlements and cattle increase in number and importance. As a consequence, Mt. Cameroon bears a belt of rain-forest from about 1,000 m. to about 2,000 m. ; this forest belt is still extant on Mt. N'Lonako, while on both Manengouba and Bambouto the belt has been broken to pieces and the prairie of the surrounding highland plains goes right to the summit. This breaking up of the forest must be rather recent, as in the Bambouto prairie we found isolated plants of tree-ferns and Clematis, both inhabiting the surviving forest patches on the same mountains.

The phytological differences in these mountains bring about important zoological differences. On Mt. Cameroon it is possible to distinguish a number of zoological zones. Beginning at 900 m., around Buea, and ending at 1,000–1,200 m., is a transition zone between the pastures and the lower limit of the rain-forest. This zone is inhabited by quite a number of insects and other animals that do not live in the forest, or in the lowlands below 600 m. : Lacertidæ, Trechinæ, Sericinæ, etc. Above this zone, five successive biological strata may be recognized. Two of them are in the rain-forest itself. The first extends from 1,100 m. to 1,500 m., and the second reaches from 1,500 m. up to 2,200 m. The insect and wood-louse faunas are widely different in these two zones. We may recall here that Engler found two phytosociological strata in the rain-forest of Mt. Cameroon and his altitudinal data fit our zoological observations well. In fact, the change of zoological aspect is coincident with the disappearance of the tree-ferns.

From 2,200 m., upper limit of the rain-forest on the south-east, up to 2,800 m., the trees have completely disappeared and the irregular lava boulders of this very strong slope (up to 50°) are covered by a short vegetation of Gramineæ, interspersed at the base with Inula and a few ferns, and higher up with a representative of the Campanulaceæ. This slope is very dry and its fauna is practically nil. From 3,000 m. to 3,500 m. the slope is much less steep ; this part has even been called 'plateau' and is deeply cleft by gulleys full of shrubs, Clematis, Adenocarpus, etc. ; on the upper ridges the tree-heather, Agauria, grows on the lava-flows, and the grass prairie is strewn with small patches of Blearia. Owing to the frequent lava-flows and to the annual prairie-fires lit by native hunters, the fauna is very poor; oddly enough, Homoptera and Diptera with a high flight-power make up the greatest part of the fauna. Coleoptera are scarce; apart from two species of Pæderus, which appear to follow man everywhere in those parts, we found only a few Carabidæ, Chrysomelidæ, Curculionidæ and Clavicornia. We could discover neither Amphibia nor reptiles.

Above 3,500 m. nothing grows but lichens and mosses, and the fauna, except for a brachypterous crane-fly, is practically nil. Running water is very scarce on Mt. Cameroon, and the aquatic fauna is poor. I could find no plankton at 3,200 m. and, from 1,500 m. upwards, we saw neither dragonflies nor caddis-flies. This paucity of the aquatic fauna has already been noted for many volcanic lands, for example, by Aubert de la Rüe in the New Hebrides.

On Mt. N'Lonako, the rain forest rises to 1,700 m., the upper range of the mountain being covered by grass prairie. The fauna is much more important than on Mt. Cameroon, both in the forest and above it, and the aquatic fauna is well represented by Gyrinidæ, a number of dragon-fly nymphs and some aquatic Hemiptera.

On Mts. Manengouba and Bambouto, as already stated, the forest is restricted to broken up patches, completely isolated in the grass fields. The terricolous fauna is rich, with a great number of Carabidæ (Agonum, Stenaptinus, Scarites), Scarabæidæ (Distellopalpus, Heliocopris); beating the bush and sweeping grass give an ample collection of Rhynchophora and Malacodermata; the Chrysomelidæ are scarcer than in the lower forest zone on Mt. Cameroon, and the Galerucinæ are particularly rare, but the Halticinæ seem much more numerous. Owing to the breaking up of the forest many grass-field animals extend to much greater altitudes on Mt. Bambouto than on Mt. Cameroon. This is especially true for all the lizards and the toads. The aquatic fauna is quite important on these two mountains, though aquatic Hemiptera are much scarcer than on the lower table-lands of East Cameroon. On both these mountain ranges the earth layer is very thin, and on Mt. Manengouba I found huge quantities of larvæ of a Cetoniine (*Dymusia cyanea*) living under the stones, on the bare rock. Many of these larvæ appear to be drowned by the heavy rains.

From a bio-geographical point of view, it is interesting to recall that many East African species or groups of species have been found on the Cameroon mountains. Such East African affinities are much clearer in the case of the fauna of Mt. Bambouto than they are in that of the fauna of Mt. Cameroon itself. In fact it appears as if the fauna of the upper ranges (above 2,000 m.) of Mt. Cameroon had been completely destroyed by the lava-flows which built the summit of the mountains, probably (B. Gèze, *C.R. Soc. Géol. France*, 15, 219; 1939) during the Quaternary. The fauna which is to be found there now is derived from the local lowland fauna. The upper ranges of Mt. Cameroon give us a splendid natural field for the study of segregation, species formation and Cuénot's theory "des places vides", the more so as the upper alpine region is separated from the upper limit of the forest by a thousand-metre zone with a very steep slope on which animal life cannot thrive. Unhappily the frequent prairie fires prevent the normal faunal reconstruction. From the fact that the lower slopes of Mt. Cameroon, from 100 m. to 1,800 m., have a fauna with distinct East African affinities, it must be admitted that this part of the mountain is much older, as old in fact as Mts. Bambouto and Manengouba. The East African character of the fauna and flora of Mt. Cameroon, without any reference to Mts. Manengouba and Bambouto, had been pointed out already by the late G. L. Bates for the birds and by Hutchinson and Dalziel for the flowering plants.

OBITUARIES

Prof. Alfred Fowler, C.B.E., F.R.S.

PROF. ALFRED FOWLER, emeritus professor of astrophysics in the Imperial College of Science and Technology, London, and late Yarrow research professor of the Royal Society, died on June 24.

Alfred Fowler was born at Wilsden, Yorks, on March 22, 1868—the seventh consecutive son of Hiram and Eliza Fowler. The family removed to Keighley about 1876, where Alfred attended various local schools. In 1880 he obtained a scholarship for the Trade and Grammar School, Keighley, from which in 1882 he proceeded to the Normal School of Science (later Royal College of Science), South Kensington, through the aid of a Devonshire exhibition. This terminated after one year, but he continued at the College as a 'teacher in training', and in 1885, at the early age of seventeen, obtained a first class associateship in mechanics. He then became assistant to Prof. (afterwards Sir) Norman Lockyer, and received some remuneration as teacher in training, supplemented by small allowances from the Solar Physics Committee. Among his pupils were many who afterwards achieved distinction—notably

Sir Richard Gregory and Mr. H. G. Wells. In June 1888, a new post of demonstrator in astrophysics was created, and Fowler was elected to fill it.

From this time until Lockyer's retirement from the College in 1901, the two men were closely associated in researches in astronomy and spectroscopy, the full significance of which became clear only after the development of atomic theory had given an interpretation of the origin of spectra. It was then seen that the classifications of stellar and laboratory spectra made on empirical grounds at South Kensington, and in the making of which Fowler took a much more active part than was generally realized at the time, provided invaluable information on the physical conditions in the sources of luminosity, and they became the foundation of the extraordinary progress in this branch of science which has been going on for the last twenty-five years and is still one of the most prominent characteristics of both theoretical and experimental research. Spectroscopy at that time found its chief, and indeed almost its only considerable, application in astronomy, and Fowler was active in day and night astronomical observation not only at South Kensington and at Westgate-on-Sea, where Lockyer had established an observatory, but also in eclipse work in various parts of the world. During his association with Lockyer he went to the eclipses of 1893, 1896, 1898 and 1900 in West Africa, Norway, India and Spain, respectively, and later he visited Spain again in 1905, made important visual observations at the partial eclipse of 1912 at South Kensington, and set out for the eclipse of 1914 in Russia, but was forced to return on account of the outbreak of war.

In 1901, when Lockyer retired from College work and a definite separation was made between the College and the Solar Physics Observatory, Fowler was appointed as assistant professor of astrophysics, and owing to reduced astronomical equipment and the rapid development of the great American observatories, he tended more and more to concentrate on laboratory spectroscopy. His astronomical knowledge and interests, however, still exercised an important influence on his work, and with studies of the series spectra of the elements he associated such outstanding discoveries as the identification of the TiO bands in the spectra of red stars, of MgH and other bands in the spectra of sunspots, and of the CO bands in the spectra of comets' tails. His work on the spectra of hydrogen and helium at once became of fundamental importance with the advent of the Bohr theory in 1913, and from that time onwards he was a leader on the experimental side in the collaboration between theory and observation which has led to the present detailed knowledge of the outer structure of atoms. He was elected a fellow of the Royal Society in 1910, appointed professor of astrophysics in the Imperial College in 1915, and in 1923, when the Yarrow research professorships of the Royal Society were established, he was elected, with Prof. G. I. Taylor, as one of the first holders of the title. He continued to work at the Imperial College and to direct spectroscopic research there until his retirement in 1934.

Of the many services which Fowler rendered to science on the side of administration and organization, it is impossible to give an adequate account in a brief space. In addition to services on the Council and committees of the Royal Society and Royal Astronomical Society (of which he was secretary from 1912 until 1918, president from 1919 until 1921, and foreign secretary from 1931 until 1936) he was, among other things, a member of the Board of Visitors to the Royal Observatory, Greenwich, a fellow founder and president from 1935 until 1937 of the Institute of Physics, a member of the Executive Committee of the National Physical Laboratory and of the Advisory Council of the Department of Scientific and Industrial Research, and, after his retirement, a member of the governing body of the Imperial College. With Fowler, these were no mere formal offices, but responsibilities which he discharged with a thoroughness and strong commonsense which were characteristic of everything he did, and perhaps even more valuable than his overt services were those which he gave spontaneously and generously without thought of return or reward. NATURE, in particular, owes much to his labours. His association with Lockyer naturally brought him into close relation with this journal, and he was a constant contributor to "Our Astronomical Column" which for many years was a characteristic feature of NATURE. But perhaps his outstanding work in this category was done in connexion with the formation of the International Astronomical Union. He had already taken a prominent part in the working of the International Union for Co-operation in Solar Research, which came to an end with the War of 1914–18, and on the formation of the International Astronomical Union, originally as an activity of the International Research Council, he was appointed as the first general secretary, and more than any other single man was responsible for establishing the Union and for the form which it afterwards took. He remained as general secretary for six years.

In later years honours came in quick succession. He was in turn awarded the Valz Prize by the Academy of Sciences, Paris, the Gold Medal of the Royal Astronomical Society, a Royal Medal, and honorary degrees of D.Sc. (Bristol), Sc.D. (Cambridge), D.Sc. (Durham), and D.Sc. (Leeds). In 1920 he was elected *Correspondant* of the Academy of Sciences, Paris, in the Section of Astronomy, and in 1926, president of Section A of the British Association. In June 1935, he was elected a fellow of the Imperial College and created C.B.E. for services to science. American astronomers acknowledged his work by the award of the Henry Draper Gold Medal for Astrophysics, and the Bruce Gold Medal of the Astronomical Society of the Pacific, and by electing him in 1938 as a foreign associate of the National Academy of Sciences.

To those who were fortunate enough to know him, however, Fowler will be remembered chiefly for his inspiration as a teacher and his never-failing encouragement and readiness to help in every way possible. His laboratory was the training-ground for many who have since achieved distinction in various spheres, and there have been numerous acknowledgments of indebtedness to his guidance and sympathy. It was his aim always to develop and never to repress the qualities he discerned in those who came under his charge, whether or not those were qualities in which he himself excelled. He leaves a widow, a daughter and a son, by whom, and by his many friends, he will be greatly missed.

HERBERT DINGLE.

Lieut.-Commander J. R. de la H. Marett

LIEUT.-COMMANDER JOHN RANULPH DE LA HAULE MARETT, R.N., of H.M.S. *Glorious*, presumed killed in action, was, like his father, Dr. R. R. Marett, rector of Exeter College, Oxford, a student of anthropology, though he approached the subject from a somewhat different angle. Like his father, however, he had a bold pioneer spirit, and was not afraid to collect and review the specialized contributions of many others with the view of showing what came of the synthesis, and what problems were raised in the whole effort to understand man, his race, culture, and environment. Like his father again, he held that all specialized contributions, including his own, must be judged in the light of their relation to the whole complex of studies. Many famous pupils of Dr. Marett will recall this constant attention to great problems and main issues, and those who knew his son, including his former teachers, will remember in him the same flair for formulating and planning the line of approach and possible solution. To the father has been given the fullness of time to show the value of his attitude to life. To the son, this longer time has been denied, but to those who knew his work, there has been ample promise of great fulfilment and much valuable and stimulating achievement.

The younger Marett served at sea during most of the War of 1914–18, and afterwards retired from the Navy to take up farming in Jersey, an island beloved by himself and his father. His main interest as a farmer was the care of a famous herd of Jersey cattle, and as editor of *The Island Cow* he contributed articles on animal genetics that attracted a good deal of attention, more particularly in America. It was this interest in genetics that brought him to Oxford, where he studied anthropology, obtaining the diploma with distinction in all subjects. Later, after a considerable amount of work elsewhere, mainly on problems of genetics, he was awarded the B.Sc. degree at Oxford, for a thesis which afterwards developed into a substantial book, entitled "Race, Sex, and Environment, a Study of Mineral Deficiency in Human Evolution" (Hutchinson 1935). Though this essay deals mainly with man, and covers a vast field, it probably grew naturally out of his earlier work on the theory that the Jersey breed of cattle is Nature's successful attempt to cope with calcium deficiency; and the same principle when extended to man suggests various lines of investigation that may well prove to be exceedingly fruitful. While it is easy for specialists in the varied fields from which he has gathered to criticize him, it must be remembered that much of his synthesis and many of his suggestions are those of a pioneer in a great adventure. His attempt to synthesize work on the soil sciences with that on the ductless glands on so large a scale opens a vast unexplored country, a land of great promise.

During the last few years, Marett was conducting an enthnological survey of Ceylon for the Government, and it is to be hoped that his researches, which have resulted in a rich store of material, will some day be published.

Leaving this valuable work on the outbreak of the present War, he once more undertook active service, and now, to the best of our knowledge, has given his life for his country. While there can be no greater gift, his friends and former teachers cannot fail to regret that a life so full of brilliant promise could not have been given, in the happier times to come, to the constructive work which he was so able to do.

T. K. PENNIMAN.

Dr. E. G. C. Poole

EDGAR GIRARD CROKER POOLE was born in Limerick, the son of Major Walter Poole, R.A.M.C., and educated at Rugby and the Queen's College, Oxford, where he was mathematical scholar. He obtained both the Junior Mathematical (1911) and the Senior Mathematical (1920) University scholarships and two first classes in the school of mathematics. He was one of C. H. Thompson's most brilliant pupils. During the War of 1914–18 he served as a lieutenant in the Intelligence Corps in France. In 1920 he was elected fellow of New College and was for a time a University lecturer in mathematics. At the time of his death he was one of the editors of the *Quarterly Journal of Mathematics*.

Poole was the most learned of the Oxford mathematicians. He had a magnificent library and he constantly read very widely in all branches of pure mathematics. He was an excellent linguist also. His published papers were mainly on differential equations, an important work on which was published by the Clarendon Press in 1936. He was a good teacher and a good colleague. He was, however, ultra-sensitive and events unconnected with himself as, for example, the depression of 1931 and the bad news of this year made him utterly miserable. Despite his fine reputation for work both as a researcher and a teacher, he felt in recent months a keen sense of depression and frustration; this produced the ill-health which led to his death in tragic circumstances on June 28.

Oxford has thus lost a fine and most erudite mathematician, and his college a delightful colleague and friend. He was forty-nine years of age.

WE regret to announce the following deaths:

Sir Alfred Bourne, K.C.I.E., F.R.S., formerly professor of biology in the Presidency College, Madras, on July 14, aged eighty.

Dr. W. E. Harper, director of the Dominion Astrophysical Observatory at Victoria, B.C., on June 4, aged sixty-two.

NEWS AND VIEWS

Organization of French Scientific Services in Britain

DR. ANDRÉ LABARTHE, as already announced, has been appointed by General de Gaulle to take charge of technical armament services and scientific research for the French National Committee. M. Labarthe, who was born in 1902, was a pupil of the late Prof. Gabriel Koenigs, and specialized in experimental mechanics. After a year in the physical research laboratories of the Ministry for Air, he went to the laboratory for physical and experimental mechanics at the Faculty of Sciences, Paris, where he became *assistant* (1931), and then *chargé de conférences* (1934). His thesis for his D.Sc. dealt with photo-electric methods of measuring pressure, the measurement of torsion, and integrating manometers. In addition, he has studied ultra-rapid cinematography, detonation, and internal combustion engines, particularly Diesel engines. M. Labarthe was the head of a delegation sent to Germany in 1934 to study the Diesel engine, and he has also visited England and the United States to inspect scientific and industrial laboratories. In France he has been technical director in the Department of Aeronautics, and recently director of the Station Nationale de Recherches d'Expériences technique and director of the laboratories at Bellevue. He has received the Plumey Prize of the Paris Academy.

On the outbreak of the War, M. Labarthe put his valuable knowledge of armaments in general, and of internal combustion engines in particular, at the disposal of the French Government, and he was recently technical director and adviser to the Ministry of Public Works. Not only did he succeed in leaving France after the general collapse, but also he managed to bring with him to Great Britain a ship carrying a valuable cargo of copper. In addition to his purely scientific publications, M. Labarthe is the author of "La France devant la guerre," a remarkable study of the 'war potential' of the belligerent nations. That book finishes with a quotation from Lacordaire which to-day has new significance: "Tant qu'un peu de sang français subsistera, la Justice aura sur terre un soldat armé".

War-time Livestock Problems: Advisory Committee

A COMMITTEE to consider war-time livestock production problems has been set up by the Minister of Agriculture. The members of the Committee are: The Right Honourable Lord Moyne, Joint Parliamentary Secretary to the Minister of Agriculture; Prof. A. W. Ashby, professor of agricultural economics, University College of Wales, Aberystwyth; Mr. A. I. Eastwood, London wholesale meat trade supervisor of the Ministry of Food; Mr. G. Gibbard, chairman of the Livestock Committee, National Farmers' Union of England and Wales; Mr. W. Graham, president, National Farmers' Union and Chamber of Agriculture for Scotland; Dr. John Hammond, Animal Nutrition Research Institute, University of Cambridge; Mr. J. Mackintosh, National Institute for Research in Dairying, University of Reading; Mr. W. G. R. Paterson, principal, West of Scotland Agricultural College; Mr. T. Peacock, president of the National Farmers' Union of England and Wales; Mr. W. J. Reid, member of the Scottish Agricultural Advisory Council. The Secretary of the Committee is Mr. H. Gardner, of the Ministry of Agriculture and Fisheries.

Registration of Engineers

THE Minister of Labour and National Service has made an order for the compulsory registration of professional engineers. Registration is with the Central Register. It refers to those who are normally engaged in a technical or supervisory capacity in aeronautical, automobile, chemical, civil, structural and municipal, electrical, gas, locomotive or mechanical engineering; and those normally engaged on research work in the engineering sciences at a university or in research and development work in any industry or as a teacher of engineering science. Men whose names are already on the Central Register are not to register again. There are 22,000 names in the engineering categories of the register, of whom about 800 are not in employment, and it is estimated that 30,000 more names will now be added.

The Rise of Turkey

A PAMPHLET "Turkey: the Modern Miracle" by E. W. F. Tomlin, published in "The Thinker's Forum" (London: Watts and Co. 6*d*. net), gives a brief review of the development of Turkey during the nineteenth century and since under Mustapha Kemal. In outlining the reforms introduced under Mustapha Kemal, while pointing out the extent to which Turkey is a totalitarian country with the People's Party as the supreme organization, its constitution is not so autocratic as might be expected. Its activities are not devoted solely to propaganda, and no institution is more democratic than the People's House or Halk Eir. Modern Turkey is impressed throughout with the spirit of youth, and Turkish education is highly practical and surprisingly democratic. The younger generation is encouraged to use its reason. A passage in the official text-book on citizenship used in all the Turkish primary schools runs: "We shall educate our children in a way which makes them capable of using their brains even in unaccustomed circumstances, of taking necessary decisions without waiting for orders from above, of developing a spirit of enterprise and a desire to overcome all difficulties which may block their way". In a tribute to Mustapha Kemal's achievements, Mr. Tomlin points out that he created a new order of society, a society liberated from the bonds of obscurantism, inefficiency and brutalizing superstition, out of material which seemed at the time to be beyond all reclamation.

War, Drunkenness and Suicide

IN a recent paper (*Brit. J. Inebriety*, 38, 28; 1940) based on his experience at H.M. Liverpool Prison which receives male prisoners from a wide area in the north-west of England and North Wales, Dr. Harvie K. Snell discusses the influence of the outbreak of the present War on drunkenness and attempted suicide, the connexion between which has often been stressed. Under the single heading drunkenness he has included not only simple drunkenness but also cases described as drunk and disorderly, drunk in charge of a vehicle and those charged at the same time with begging and common assault. His figures show the somewhat surprising result that there was a definite decline during the first four months of the War as compared with the previous three years in the number of persons admitted to prison for drunkenness or attempted suicide.

These results are in striking contrast with the late Dr. Sullivan's results concerning convictions in women for the same two offences in 1914, which both showed a marked increase after the outbreak of war, but present the same trend as the figures relating to women admitted to the Manchester Prison from an extensive area in the north-west of England and Wales for drunkenness and attempted suicide in the early months of the present War. Dr. Snell attributes the decline in the incidence both of drunkenness and of attempted suicide on the present occasion to economic and social as well as psychological causes, the former including rise in the price of liquor and the condition of the streets in the black-out period, and the latter the lesser degree of emotional strain leading to drunkenness than that which occurred in 1914.

Colonel Kenneth Macleod

COLONEL KENNETH MACLEOD, an eminent military surgeon and hygienist, was born in the Outer Hebrides on July 23, 1840, the son of a Free Church minister. He received his medical training in the University of Edinburgh, where he qualified in 1864. After four years service in the Indian Medical Service, he was appointed secretary to the Inspector-General of Hospitals in 1872 and held this post until 1879. On December 1, 1879, he was made professor of anatomy in the Calcutta Medical College, a post which he held until his retirement in 1892. Macleod did much for the advancement of medicine in India. In 1869 he investigated Indian cattle plague and set about establishing facilities for veterinary research in India, which culminated in the foundation of the Bengal Veterinary College. In addition to his surgical activities, he took an active part in public work. He founded the Calcutta Medical Society, was its first secretary and later its president, and was editor of the *Indian Medical Gazette* during 1871–92. After his return to England on his retirement, he was appointed professor of clinical military medicine at the Army Medical School at Netley, and held this post until 1905. He died on December 17, 1922.

Early Man and Pleistocene Deposits in America

ALTHOUGH it is established by the find in New Mexico of a Folsom projectile point embedded in fossil mammalian vertebræ that early man in America was contemporary with and hunted an extinct form of bison, the absence or ambiguous character of stratigraphical evidence and associations of a majority of finds of early American stone age industries hitherto have made it impossible to determine with certainty either their age or their place in a cultural sequence. The relation of the Folsom point, for example, to the Yuma type, which typologically is simpler or more primitive, remains obscure, though the finds recently reported from the south-western States indicate a possibility of establishing sooner or later a cultural sequence leading up to Folsom man, and this is brought nearer to being realized by the discovery of the so-called Sandia man, whose existence is inferred from artefacts found in the basal layers of a cave of the Sandia Mountains, near Albuquerque, New Mexico. These artefacts would appear to be the earliest relics of human purposive activity as yet discovered on the American continent. Here, during the past three years, numerous relics of an extinct fauna mingled with human artefacts have been found, of which the stratigraphic sequence has been fully established in recent excavations.

Frank C. Hibben, writing in the *Scientific American* of July, gives a brief outline of the sequence of deposits found in the Sandia Cave. It begins with the surface deposits of dust with which were mingled pottery and other relics of the Pueblo age. Beneath this a layer of stalagmite deposited in a pluvial period sealed late Pleistocene deposits, in which debris bone fragments and soil were consolidated into a homogeneous mass by calcium carbonate. In this material were chips of flint, scrapers and points, among them the true Folsom points. Beneath this Folsom layer was a thick deposit of yellow ochreous laminated material, evidently water-borne, deposited in a second pluvial when the cave was not in use. Beneath this, and between it and the floor of the cave, was the accumulation of a dry period showing the earliest evidence of occupancy of the cave—fragments of bone, evidence of fires, and stone implements. The implements include shouldered points, entirely different from the Folsom point, and said to be comparable to European palæolithic types. By a hearth lay a blackened fragment of the jaw of a camel. It would thus appear that the evidence from the Sandia cave not only points to the existence of Folsom man in late Pleistocene times, but also has established on indubitable stratigraphic evidence the appearance of more primitive culture in a considerably earlier period, contemporary with an extinct Pleistocene fauna.

The Canadian Entomological Service

UNDER this title, Dr. Arthur Gibson, Dominion entomologist, Ottawa, has discussed the more important developments in applied entomology in Canada during the past fifty years. His paper is published in the Transactions of the Seventh

International Congress for Entomology, held in Berlin in 1938, pp. 1429–1479. James Fletcher, in 1887, incepted studies on insects injurious to Canadian crops and in that year he became the first Dominion entomologist. Prior to this time he had acted for a few years in an honorary capacity. On Fletcher's death Dr. Gordon Hewitt, of the University of Manchester, succeeded to the post thus vacated: he held office from 1909 until 1920. In the last-named year the death of Hewitt led to the appointment of Mr. (now Dr.) Arthur Gibson as the Dominion entomologist.

The Canadian Entomological Service has steadily developed each year and has attained a commanding position in the Dominion Department of Agriculture at the present day. Both Fletcher and Hewitt contributed much to its growth and their good work has been worthily upheld and extended by Gibson. Field stations and laboratories are maintained at thirty different localities and there are ten plant inspection stations. When, however, it is recollected that the provinces Manitoba, Saskatchewan and Alberta alone, are larger than France, Germany and Italy combined, it will be realized that Canadian entomologists have no lack of problems to contend with. The Dominion Entomological Service now ranks as the most important of its kind in the British Empire.

Vegetative Propagation in Tropical Plantations

THE Imperial Bureau of Horticulture and Plantation Crops, East Malling, has issued Technical Communication 13 on this subject by G. St. Clair Fielden and R. J. Garner. It deals with the vegetative propagation of some fifty-five plantation crops, and follows a previous communication (issued in 1936) dealing with the vegetative propagation of some one hundred fruit varieties grown in the tropics and subtropics. The help of technical experts has been invoked for adequate treatment of such major crops as rubber, coffee, cacao, etc., while the foreign literature has been thoroughly combed for details of propagation of the less familiar, but nevertheless important, crops. One feature of the previous work, which commended it also to workers in temperate regions, is retained and considerably enlarged, namely, the section devoted to methods used in vegetative propagation. The descriptions are supported by simple, clear, line drawings of some seventeen types of graft and seven types of budding commonly used in vegetative propagation. Tropical workers will also be glad of the illustrated detail of the construction of loosely woven potting baskets which have been found so useful a substitute for pots in nursery work in the tropics. For those who wish to study originals, a list of references immediately follows the discussion on the propagation of each particular crop.

Weeding Methods in Teak Plantations

A. L. GRIFFITH, provincial sylviculturist, Madras has recently discussed an investigation into different weeding methods in the formation of teak plantations in areas with a west coast climate (*Indian For. Rec., Sylviculture*, 4, No. 2; Govt. of India Press, New Delhi, 1939). The investigation was carried out on a number of small-scale experiments and four large-scale ones. Five methods of weeding were tried. At the time, the principal method of weeding the young teak was by the expensive way of forking. The experiments carried on since 1932 have demonstrated that the method termed scraping is cheaper and as efficient on light forest soils; and that other methods, such as the cheap weeding by weed cutting alone, are not worth while. Weed cutting by hand is by no means cheap in England. By the scraping method it is said that plantation costs are being reduced by Rs. 10 per acre and the quality is as good as formerly. The scraping is done in 4 ft. strips (2 ft. on each side of the line of plants). Weed growth was not cut before. The scraping is effected with an ordinary *mammoty* (like a pointed spade with a recurved handle), removing about ½ in. of soil and cutting the weed roots at that depth below the original soil-level. The weeds removed are piled on the 2 ft. unweeded strips between the lines without cutting the weed growth on them. Or the operation may be carried out over the complete area, the weeds being then presumably removed.

Equine Encephalomyelitis in U.S.A.

IN an editorial article in *Public Health Reports* of April 5 the writer remarks that though equine encephalomyelitis may have existed for very many years in the United States, attention has recently been focused on it by the epidemic in Massachusetts in 1938 when human cases of encephalitis also occurred. There was, however, no indication of human contact infection in these cases. In 1939 only 8,000 cases of equine encephalomyelitis were reported in the United States, or only about 4 per cent of the number (184,662) reported in 1938. The incidence was 1·1 per 1,000 animals (horses and mules) in the affected counties and a case fatality of 30 per cent. The highest incidence was reported from counties in the far-western and Pacific States, a north-east–south-west strip of the central States and three Atlantic States, New Jersey, North Carolina and Florida. As in previous years, more than 90 per cent of the cases occurred in the summer or early autumn, This seasonal prevalence favours the current view that the principal means of transmission is by blood-sucking insects, especially mosquitoes. The prophylactic value of vaccination with a vaccine of chick embryo tissue is shown by the fact that the incidence of encephalomyelitis in vaccinated horses and mules was 0·37 per 1,000 in the vaccinated as compared with 1·2 in the unvaccinated. Other factors in the reduction of the disease were the retarding of insect breeding and increased resistance owing to previous attacks among the animals.

Vehicle Radio-Telephone Service

IT is reported from Pittsburgh, Pa., that the Bell Telephone Co. has applied for a permit to install transmitters and receivers on what is called a 'tie-up' with existing telephone facilities. The company has applied to the Federal Communications Commission in Washington for permission to place transmitting and receiving equipment on the top of its Pittsburgh building and at certain suburban situations. With this service available, any private or commercial telephone subscriber could converse with the occupants of a properly equipped motor-vehicle moving on the street or highway within a radius of fifteen miles. Each truck or motor-car equipped for the service would have its own telephone number, and would be reached through a special operator, who would handle these calls. It is to be known as the 'vehicular radio-telephone service' (*Elect. Rev.*, June 7).

The Bell Telephone Company's present plans include making the service available to public utility company vehicles and equipment, up to seven of its own vehicles. This would permit quick mobilization and centralized direction of motor vehicles in the event of major emergencies. There are at present limitations on the number of channels available. Otherwise, even at high cost, there would be an appreciable public demand for such telephone installations in privately owned cars. The limitation of the channels will restrict the spread of the service, but in the case of many hospital and police ambulances it should prove very useful.

Rising Cost of Generating Electricity

METHODS are being discussed by electrical engineers to meet the rising costs of generating electricity. Even before the War this was becoming a serious problem. In some cases it had rendered the raising of tariffs inevitable. It apparently was the only alternative to bankruptcy, and the War has certainly not improved the situation. The Electricity Commissioners not long ago published a list of these changes. According to the *Electrical Times* of July 11, Sir Percival Bower, chairman of the Birmingham Electricity Department, made a speech on July 2 in which he stated that his committee is anxious to avoid any increase in tariffs, notwithstanding the formidable increase in costs all round. A fairly large surplus on the last year's accounts is being carried forward to cover any emergency expenditure. Another way of coping with the rise in costs is proposed by Mr. F. H. Whysall of Belfast. If, he says, the department is to pay its way and have a reasonable balance for renewals and reserve accounts, it is impossible to maintain the present low level of charges to the consumer. He intends to recover these increased costs by an equitable method, taking into account the rise in prices of coal, stores and wages. The large consumer is easily assessed, he already has a coal clause in his agreement and he will now feel the effect of other rises in commodities or wages on a similar sliding scale. The principle cannot be applied so precisely to the ordinary consumer, but it happens that an approximation is fairly represented by charging him a round figure of 10 per cent extra for the present, prior to the inclusion of a similar kind of coal clause in his bill. As for the slot-meter house-holder, he will lose his five per cent cash discount.

Development of Rural Electrification in England

SINCE the War began, there is evidence that the sales in Britain of electric milling and dairy equipment have been increasing. In addition, many rural supply authorities find that inquiries as to costs and running expenses of various types of electric motors and pumps are being made on an increasing scale. On the other hand, the extensions to isolated farms will be both more difficult and more costly owing to the rise in the price of materials. In the *Beama* journal of May, it is pointed out that if the War continues for two or three years, it will be necessary for the Government to see that these extensions are carried out in the interests of the better utilization of farm labour. But a question of greater importance is the connexion of farms which are not making a full use of supply mains quite close to them. Just before the War, the most encouraging feature of rural electrification was the willingness of landlords to bear the capital cost of connecting up electric supply, the tenants paying the interest charges. There is also scope for the County War Agricultural Committees to facilitate the group interconnexion of farms. The sanction of the Ministry of Agriculture would have to be sought before these committees could act in this way. The Ministry would probably be sympathetic. Concern is being felt about the problem of threshing on isolated farms, which either possess no tractor or should be making the full use of the farm tractor when it may be desirable to thresh as well. Amongst problems which cripple development of electric power are the high rates customary in times of emergency, and also the cost of the necessary way-leaves negotiations which sometimes, for an isolated farm, cost as much as ten per cent of the total cost of giving supply to the farm.

Agricultural Literature

THE expansion of the Rothamsted Library since the first edition of a catalogue in 1926 has made a new edition necessary (Rothamsted Experimental Station, Harpenden. Library Catalogue of Printed Books and Pamphlets on Agriculture Published between 1471 and 1840. Second Edition 1940. Pp. 293+1 plate. 12*s*. Paper Covers; 15*s*. Cloth Covers). It has been compiled by the librarian, Miss Aslin, who has not merely listed a number of books, but has also added interesting notes on them and their authors. This edition contains two new sections, one including manuscripts and farm account books, the other listing the collection of prints of farm animals which the library possesses.

The catalogue only covers the period 1471–1840, as the books published since the latter date are too numerous to be included in one volume. The period selected is well chosen, for the dates marking its limits are milestones in the history of agriculture. In 1471 the first printed book on agriculture appeared, namely, the Augsburg edition of Petrus Crescentius' "Epistola in librorum comodorum ruralium", and in 1840 Liebig's "Organic Chemistry in its Application to Agriculture and Physiology" was published, thus definitely marking the end of the purely empirical period of agriculture and the beginning of the application of scientific principles. The catalogue is excellently arranged for the use of students: an alphabetical list of English authors and translations is followed by a similar list of foreign authors and translations, and these latter are also catalogued under the headings of their respective countries. This publication is invaluable not only for students of agricultural history and bibliography, but also for students of horticultural history, since there are numerous references to the early herbals and to treatises on gardening, particularly on the cultivation and propagation of fruit trees.

Springtime the Safest Time

UNDER this title the March issue of the *Statistical Bulletin*, which in spite of its austere title is remarkable for the sprightly character of its contents, illustrates the fact that life and limb are safer in the spring than at any other time of the year by the statement that, if all the year were April, the annual toll of fatal accidents in the United States would be 12,500 fewer than it has been in recent years. During the period 1934–37, the average number of deaths daily from accidents, particularly burns, falls and motor accidents in the United States was 285, whereas during the same years the daily average for April was 251, as compared with July, the worst month, when the average daily toll was 367. The deaths in March and May averaged only a few more daily than in April. In conclusion, the writer recommends that the spring should be the season not only for cleaning the house and making necessary repairs, but also for clearing out "the junk of the mind—the complacency of fixed daily habits which are fraught with hazards".

Earthquakes Registered at Hong-Kong

DURING January, twenty-two earthquakes were registered at the Royal Observatory, Hong-Kong, the greatest number on any one day being four on January 6. The greatest shock recorded was probably that of January 17 at 1h. 21m. 25s. G.M.T., which exhibited a full complement of phases, and showed maximum amplitudes of 10·4 mm. on the north–south component and 8·7 mm. on the east–west component of the Milne-Shaw seismographs. The difference in arrival time of the primary and secondary waves for this earthquake was 5 min. 17 sec., which, according to Jeffreys' latest tables (*Mon. Not. Roy. Astro. Soc.*, Geophysical Supplement, 1939, June), on the assumption of a normal depth of focus gives an epicentral distance of just over 33° from Hong-Kong.

Recent Earthquakes

THE United States Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association has determined the epicentres of the earthquakes of June 3 and 5. On the basis of reports from sixteen stations, the provisional epicentre of the earthquake of June 3 was lat. 25° N., long. 110° W., which is in the Gulf of California to the east of the island of San José. On the basis of reports from twenty seismological stations, the epicentre of the earthquake of June 5 was lat. 68° N., long. 138° W. This is in the Richardson range of mountains in the extreme north-west of Canada. Both areas are susceptible to earthquake shocks, having experienced them in the past, and both the earthquakes were comparatively large. The first was registered at Kew on June 3 at 18h. 17m. 43s. G.M.T., and the second on June 5 at 11h. 10m. 59s. G.M.T. The second was the larger, having a maximum ground amplitude of 43 μ at Kew. Further moderately large earthquakes were registered at Kew on June 17, 18, and 22, also on July 1 and 6. Information is awaited from other observatories before details of these shocks can be given.

Leverhulme Research Fellowships for 1940

THE trustees of the Leverhulme research fellowships have made awards tenable for varying periods up to two years, for research in the subjects indicated, to the following, among others: Prof. J. R. Bellerby, formerly Brunner professor of economic science, University of Liverpool, post-War economic reconstruction; Dr. R. M. Davies, lecturer in physics, University College, Aberystwyth, experimental investigations on turbulent flow in an air tunnel (renewal of present fellowship); Dr. A. G. Gaydon, Radiation Gas Research Fellow, Imperial College, London, a spectroscopic study of combustion processes in flames and explosions; Dr. N. A. V. Piercy, reader in aeronautics, University of London, mathematical theory of wing sections; W. H. Warburton, Fircroft College, Bournville, a survey of the North Staffordshire pottery industry.

Announcements

MR. J. C. CROCKER has been appointed head of the Department of Chemistry, Chelsea Polytechnic, London, following the retirement on August 31 next of Mr. C. Dorée, who has held the post during the last sixteen years. Mr. Crocker has been senior lecturer on the staff of the Department of Chemistry for many years, during which time, in addition to taking his share in the preparation of a large number of students for their first degree in the University, he has done highly successful work in the training and direction of research students of the Polytechnic for the higher degree in chemistry of the University of London.

IT is announced by the Institution of Naval Architects that the Institution's Library has now been completed by the erection of the memorial to the late Sir Archibald Denny. The Library is situated at the offices of the Institution at 10 Upper Belgrave Street, London, S.W.1.

DR. FRED C. KOCH, professor of physiological chemistry at the University of Chicago and chairman of the Department of Biochemistry, has been appointed Frank P. Hixon distinguished service professor of chemistry in succession to Dr. Anton J. Carison, who will retire at the end of this year.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Classification of Sub-human Types

DURING the last fifteen years scarcely a year has passed but a new skull has been discovered of a type of primitive man or of a higher ape allied to man's ancestors. We are thus getting a large series of forms which have to be classified, and we are having much new light on the origin of man. Perhaps within a hundred years we may have all the main links between man and an anthropoid such as Dryopithecus, with dozens of forms in side branches, which have left no descendants. But a difficulty will arise in nomenclature.

If we have a line of forms from, say, a primitive Eocene horse like Eohippus to an Oligocene horse like Mesohippus with every connecting link, are we to regard all as belonging to Mesohippus ?

Among the early human types a similar problem is arising. Zuckerman says, "At the present time there does not seem to be any more reason than there was ten years ago for separating generically from one another in classification such archaic types as Sinanthropus, Pithecanthropus, Neanderthal and Rhodesian man"[1]. If these four types are placed in the same genus, that genus will have to be Homo. Zuckerman further suggests that there is "no reason to regard Java man (Pithecanthropus) and Pekin man (Sinanthropus) as generically distinct. This view was reaffirmed last year by Le Gros Clark and has just been restated by von Koenigswald and Weidenreich".

Montandon, on the other hand, considers that Pithecanthropus stands outside the Hominidæ, while he regards Sinanthropus as a more advanced type which is definitely within the Hominid group. While such a difference of opinion exists it would surely be unwise to have the Pekin man called *Homo pekinensis* and placed in the Hominidæ, while an allied species of the same genus is called *Homo erectus* and placed in a different family.

It may be some years before we are in a position to state definitely the affinities of such types as Pithecanthropus and Sinanthropus, and even to be at all sure whether Sinanthropus is closely related to either Neanderthal man or Rhodesian man, and it seems to me nothing will be gained at present by putting all these four types in the genus Homo.

Further, to place Pithecanthropus in the genus Homo commits us to a definite conclusion which may or may not be correct ; and, while the majority of anatomists at present agree in regarding Pithecanthropus as a primitive type of man, there are, and have always been, many who regard it as distinctly sub-human. Even should it prove to be the ancestor of man, I cannot see any reason why it should not be left as Pithecanthropus, while there are very definite objections to placing it in the genus Homo. Pithecanthropus with a brain of 800–950 c.c., an enlarged canine tooth in the male and a diastema in front of it, may belong to the same genus as Dean Swift with a brain of 2,100 c.c., but at present many, and even Dubois himself, still have doubts.

Radioactivity of Be^{10}

WHEN beryllium is bombarded with deuterons, a group of protons is observed, with a range of about 26 cm., which is attributed to the reaction Be^9 (H^2, H^1) Be^{10}. It has been assumed that the product of this reaction is the species which McMillan[1] found in a beryllium target after prolonged bombardment. Recently, Pollard[2] has reported that the activity in question decays with a period of 350 years. This figure was obtained from the number of protons emitted (which indicates the number of beryllium nuclei formed) and the number of electrons from the decaying substance. Further, the latter author found that the maximum electron energy was about 0·75 Mv.

This high electron energy in combination with the long life at once leads to the necessity that the transition involved is at least doubly forbidden, as one can verify by inspection of the Sargent diagram. If this is so, it leads to the conclusion that the ground states for Be^{10} and B^{10} are not both S states as suggested by Feenberg-Wigner and Hund[3], unless a γ-ray follows the transition. In order to obtain further information about the radioactivity of Be^{10}, I tried to produce it by another method which would allow of its concentration in a small amount of matter. For this purpose boron was irradiated with slow or fast neutrons, which leads either to Li^7 and an α-particle, or to Be^{10} and a proton.

To make the method as sensitive as possible, about 700 gm. boric acid were placed around a lithium target which was bombarded with 900 kv. deuterons. The Be^{10} was separated chemically after 10 mgm. beryllium had been added as carrier. The beryllium oxide was tested inside a counter so designed that even very soft particles could be detected. Since the neutron source emitted, at the voltage used, and for a current of 100 μ amp., $1{\cdot}8 \times 10^{10}$ neutrons per second, and the total dose was 700 μ amp.-hours, the total number of neutrons passing through the substance was $4{\cdot}4 \times 10^{14}$. As one electron per second could certainly have been detected, an upper limit for the cross-section of this reaction can be found if Pollard's value for the decay constant is accepted. σ becomes, as calculated from the above figures and the geometry, about $\leq 2 \times 10^{-28}$ cm.^{2} ; this representing a mean value for the inhomogeneous neutron beam.

This value is far smaller than could reasonably be expected, as the reaction is slightly exothermic and should take place with considerable ease with fast neutrons. This result must mean either that the reaction is for some reason extraordinarily improbable, or that the activity observed by Pollard and McMillan is in fact not Be^{10}, since the decay constant determined by Pollard can scarcely be in error by several powers of 10. Support for this last suggestion lies in the circumstance that the activity from a beryllium target has not been identified chemically by the previous observers.

I am greatly obliged to Dr. N. Feather for the loan of his counter and to Mr. W. Birtwhistle for technical assistance.

Note added on proof: R. D. O. Neal and M. Goldhaber (*Phys. Rev.*, 57, 1086) have shown that the observed activity of Be on deuteron bombardment is due to H^3.

Cosmic Ray Intensities in Relation to Cyclones and Anticyclones

IN a previous letter[1], we showed that cosmic ray intensities undergo characteristic changes during the passage of cyclones. The computations were carried out for cyclones irrespective of any seasons. Since, however, the paths of cyclones are generally subjected to seasonal variations, it is possible that the seasonal effect of cosmic ray intensities is superimposed on the results there obtained. We therefore followed the procedure as mentioned below, which enables one to eliminate the seasonal effect. The results thus obtained corroborate the previous conclusions. The same method was also applied to anticyclones.

We used nearly the same hourly means of cosmic ray intensities, 362 in number, observed during the traversal of the same 11 typical cyclones as were chosen in the previous letter, the only minor difference being the rejection of two unimportant cases which were disturbed by magnetic storms. The same method of representation on a polar diagram was also followed as before. Instead of writing down, however, the values of cosmic ray intensities themselves on the sections of the diagram corresponding to the positions of Tokyo, we put down their percentage deviations from the mean intensities during the passage of individual cyclones. In this way we obtained the mean percentage deviation for each section as given in Fig. 1, which shows the variation of cosmic ray intensities due to cyclonic migration free from the seasonal effect. As can be seen from the figure, the general features are nearly the same as in Fig. 2 of the previous note, although the magnitude of the variation is less, namely, ± 0·5 per cent in this case.

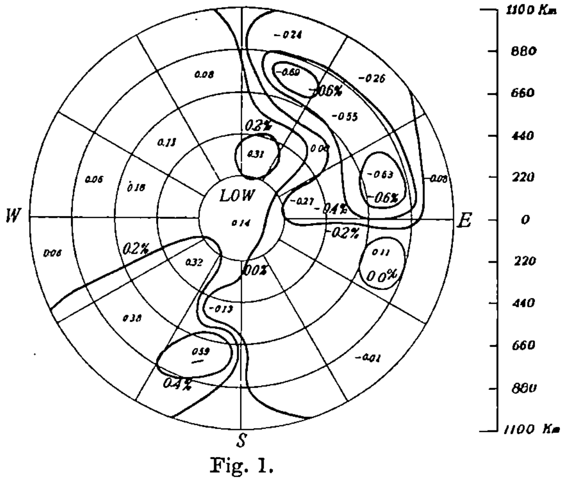

Fig. 1.

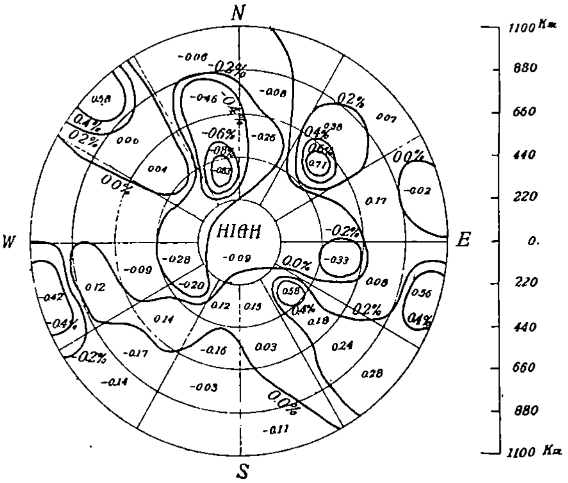

Fig. 2.

Exactly the same procedure was adopted for 25 cases of anticyclones, the centres of which were determinable within a radius of about 1,100 km. from Tokyo as before. Corresponding hourly means of cosmic ray intensities, 598 in number, were treated in the same way as above. The final results thus obtained are given in Fig. 2, in which the distribution of intensity deviations is more complicated than that of Fig. 1. Since the anticyclone traverses the area in question from west-north-west to east-south-east, carrying cold air masses of polar origin in the front and warm air masses of tropical origin in the rear, the general feature of Fig. 2 seems again to illustrate the fact that the arrival of a cold air mass tends to increase the intensity of the hard component of cosmic rays, while that of a warm air mass tends to decrease it, in conformity with the instability of the meson. The high values, however, in the north-west quadrant as well as in the south-west quadrant, as shown in Fig. 2, seem to show that the warm rear of the anticyclone is again followed by a cold air mass. Whether this is due to the cold front of the succeeding anticyclone or to the specific character of the anticyclone itself will be seen in the future.

This work was done as a part of the programme of the Cosmic-Ray Sub-Committee of the Japan Society for the Promotion of Scientific Research.

Crystal Structure of Rochelle Salt

We have succeeded in finding approximate positions for all the atoms of Rochelle salt (sodium potassium tartrate tetrahydrate) in the crystal structure. The unit cell has dimensions 11·93 A. × 14·30 A. × 6·17 A. ($Z = 4$), and the space group is $P2_12_12$. The set of general positions expressing this symmetry is

$$xyz\,;\ \bar{x}\bar{y}z\,;\ \tfrac{1}{2}+x,\ \tfrac{1}{2}-y,\ \bar{z}\,;\ \tfrac{1}{2}-x,\ \tfrac{1}{2}+y,\ \bar{z},$$

and the co-ordinates of the various atoms are as follows (expressed in sixtieths of the cell edges):

2K on	(0 0 3)	4O on	(15 24 51)
2K	(0 30 9)	4O	(3½ 21½ 49)
4Na	(15 0 30)	4OH	(9½ 21½ 19)
4C	(9 11½ 18)	4OH	(15 14 38)
4C	(7 16½ 27)	$4H_2O$	(27 18 1)
4C	(9½ 16 39)	$4H_2O$	(23½ 4½ 30)
4C	(9½ 21 49)	$4H_2O$	(15 3 51)
4O	(7 6 20)	$4H_2O$	(25 24 26)
4O	(13½ 11 8)		

We are not satisfied with the accuracy of these positions; but we have no doubt that our general idea of the structure is correct. It agrees with two-dimensional Fourier syntheses projected down the *a* and *b* axes (the signs of the *F*'s being obtained from intensity changes in the differently substituted salts) and also with a three-dimensional Patterson diagram of the ammonium salt, for which all the intensities were observed. All the interatomic distances are reasonable. The water molecules seem to be either of the three- or the four-bonded type. They co-ordinate the sodium and potassium atoms and assist in bonding these to the tartrate molecule. The tartrate molecule itself has an extended carbon chain with the two identical halves of the molecule lying in two planes inclined at 60° with one another.

It is hoped to derive more accurate positions and to publish a fuller account of the structure very soon.

Calculation of Energy Absorbed in Irradiated Tissue

In a previous letter[1], a method was outlined for the volume integration of dosage for X- and gamma-ray beams of radiation. The result of the calculations for a beam of X-rays passing through a 'water phantom' from a 200 kv. Metropolitan-Vickers X-ray tube filtered through 1 mm. copper and 1 mm. aluminium at a focal skin distance of 40 cm. showed the integrated dosage R, to be

$$R = 5{\cdot}6 \times Ar_0 + \frac{Ar_0}{0{\cdot}085}\left(1-e^{-0{\cdot}085(x-5{\cdot}6)}\right), \quad (1)$$

where A is the area of the applicator at the skin surface and r the maximum skin dose for a large applicator (20 cm. × 15 cm.).

When applied clinically, the above formula allows of comparison of energy absorbed by patients during treatment; but for the computation of absolute energy further calculations are necessary. A method of deducing these absolute values using the ionization method of measurement in small air chambers in the irradiated material has been devised by Gray[2], who states that . . . "If secondary beta radiation is being generated in a medium M at a rate E_v ergs/c.c./sec. then the rate of production of ions in a gaseous medium enclosed in a small cavity in M is $J_v = E_v/W\rho$ . . . . (2), where W is the average energy lost by a beta particle per pair of ions produced and ρ is the ratio of the stopping power of M and the gaseous medium for the particles concerned". Since R is the total integrated dosage in a volume V, then $\int_0^V J_v dv = R/t.e$, where e is the charge in E.S.U. on an electron, and t the time in seconds to liberate the charge. The energy absorbed from an X-ray beam passing through a homogeneous medium is therefore

$$E = \frac{R \times W \times \rho}{e} \quad . \quad . \quad (3).$$

The validity of this equation, however, depends on certain definite conditions[2]. On applying these to the present problem, it is seen to be essential that the material of the absorbing phantom and the dosimeter walls have the same value of ρ, and that the ratio of loss of energy of a beta particle producing an ion pair in air and in the medium be known. The results[3] used in the calculation of integrated dosage were obtained by means of dosimeters the walls of which had approximately the same mean atomic number and electronic density as the water of the phantom; but these walls had been rendered conducting with a film of graphite. Thus the assumption that ρ is the same for dosimeter walls and water is not correct, but for clinical work where homogeneity is non-existent, and the electronic density of tissue only approximates to that of water, the results may be regarded as sufficiently accurate.

The ratio of the number of electrons per c.c. in air at N.T.P. and in water is $0{\cdot}858 \times 10^3$; then the quantity of charge T liberated in tissue as compared with air is given by

$$T = R \times 0{\cdot}858 \times 10^3 \text{ E.S.U.}$$

The energy liberated in tissue is $E = \dfrac{R \times W \times 0{\cdot}858 \times 10^3}{4{\cdot}77 \times 10^{-10}}$;

where W, the mean energy required to produce an ion pair in air, is 32·5 eV. or $5{\cdot}2 \times 10^{-11}$ ergs. (Since this letter was written, it has been shown by Lasnitzki and Lea[4] that the relative ionization in tissue for equal ionization in air for gamma and hard X-rays is 1·12; thus the energy absorbed in tissue from the beam considered above is probably 12 per cent greater than the value given.) In water with a mean atomic number of 3·33, W (water) becomes $1{\cdot}04 \times 5{\cdot}2 \times 10^{-11}$ ergs. The expression, therefore, for the total absorption of energy in tissue during irradiation is

$$E = \frac{R \times 1{\cdot}04 \times 5{\cdot}2 \times 10^{-11} \times 0{\cdot}858 \times 10^3}{4{\cdot}77 \times 10^{-10}} \text{ ergs};$$

or $E = 97R$ ergs or $2{\cdot}32 \times 10^{-6}\ R$ calories. This value is necessarily approximate for the reasons stated above, and for absorption in bone modified values of ρ and W have to be introduced.

A more detailed discussion of the above is to be given at a later date.

The Evolution of the Stars

Drs. Hoyle and Lyttleton have raised[1] some objections to the results of the application of nuclear physics to the problems of stellar evolution as discussed in my recent articles on this subject[2].

The main difference between the two points of view consists apparently in the fact that, whereas I maintain that the stellar mass remains essentially constant during the evolution, Hoyle and Lyttleton are of the opinion that the stellar energy, although manifestly due to nuclear reactions, actually comes from the cosmical material collected by stars on their way through space. It is easy to see, however, that the rates of accretion as calculated by Hoyle and Lyttleton[3] are too high by a factor of many thousands, because they have not taken into account the thermal motion of the particles of the interstellar gas. This has led them to a formula according to which the amount of matter collected by a moving star is inversely proportional to the cube of its velocity. It is known, however, that, due to the interaction with the light quanta of interstellar radiation[4], these particles must possess thermal velocities as high as 15 km. per sec. (for hydrogen). These high velocities reduce quite considerably the effective cross-section for capture, and the hydrogen collected can scarcely secure more than one twenty-thousandth part of the radiation of typical giants.

Also, I cannot agree with Hoyle and Lyttleton that "the basis of nuclear theory is in need of revision" in order to make possible the building-up processes in the stellar interior. Our present knowledge concerning the possible nuclear reactions is too well established (both experimentally and theoretically) to make any such revision possible. Thus, Weizsäcker's[5] view that the elements are older than the stars remains the only way out.

The remark of Hoyle and Lyttleton that in my articles "no attempt is made to account for the three distinct periodicity groups of pulsating stars" is apparently due to the fact that they have overlooked the whole discussion pertaining to Fig. 2. In fact, the existence (disputed at present) of these three groups represents the best argument in favour of my views.

Finally, I quite agree with Messrs. Hoyle and Lyttleton that the problem of complex stellar groups (binaries and clusters) is still awaiting resolution.

G. Gamow.

George Washington University.
March 1.

[1] Hoyle, F., and Lyttleton, R. A., Nature, 44, 1019 (1939).

[2] Gamow, G., Nature, **144**, 575, 620 (1939).

[3] Hoyle, F., and Lyttleton, R. A., *Proc. Camb. Phil. Soc.*, (4), 35 (1939).

[4] Dunham, T., *Proc. Amer. Phil. Soc.*, 8, 277 (1939).

[5] v. Weizsäcker, C., *Phys. Z.*, 39, 633 (1938).

Prof. Gamow appears to agree with our view that accretion of hydrogen by the stars from the cosmical cloud would be important if the rate were sufficiently rapid to compensate the transmutation of hydrogen within the stars. He believes, however, that the accretion rate is too low for this to be happening in the case of a typical giant by a factor of order 10^4. Since the publication of our initial paper[1] on this problem, we have been able to proceed further with the discussion of the physical aspects of the process, and we have been able to show that in reality the difficulty mentioned by Prof. Gamow does not arise.

The accretion rate is proportional to ρ, the density of the cosmical cloud, and in our earlier papers we took an averaged value for ρ. But in certain regions of the galaxy, for example near the galactic plane, the density is probably much higher than the average for the galaxy as a whole. In addition, it has appeared from recent observational work[2] that the average value of about 2×10^{-23} gm. per c.c. at first taken by us may be too small by a factor of about 4. Combining these effects, we have shown[3] that the density probably exceeds 10^{-21} gm. per c.c. in exceptional regions of the galaxy, and the massive stars are regarded as being confined to these regions, thereby giving a natural explanation of such dynamical features as the marked concentration of massive stars towards the galactic plane. In this way a factor of 10^2 is accounted for from the discrepancy urged by Prof. Gamow.

The remaining factor has arisen on account of the assumption by Prof. Gamow that the cosmical cloud everywhere possesses high thermal energy. It now appears from recent work[3] that in regions of density 10^{-21} gm. per c.c., the presence of even a small proportion of hydrogen molecules (of order 10 per cent, say) will prevent any appreciable temperature being maintained by the cloud. The reason for this is that the translatory energy of motion of the particles of the cloud must be in equilibrium with the internal energy of the molecules, since the thermal and internal energy tend to reach equipartition as a result of collisions within the cloud. Thus the effect of collisions is to excite the vibrational and rotational levels of the $^3\Sigma$ state of the molecules, and this internal energy can be radiated by quadrupole transitions to the ground state of the molecules. In a cloud of density 10^{-21} gm. per c.c., the time between successive exciting collisions of a particular molecule is of order 10^7 sec., whereas the lifetime for a quadrupole transition of the excited molecule is only about 10^2 sec. Consequently the molecules radiate away the energy supplied by selective absorption, and it can readily be shown that the cloud will take up a temperature of approximately $6\sqrt{Tx/y}$, where T is the temperature of the source of radiation illuminating the cloud, x is the proportion of material in ionized form and y is the proportion in molecular form.

For the purpose of applying this result to the accretion process, it is only necessary to show that an appreciable proportion of the cloud is in molecular form at a distance from the star of the order of the capture radius, since it must then follow that the material near the capture radius cannot rise to high temperature either by selective absorption or as a result of collisions caused by the gravitational field of the star. This question is of particular interest in relation to stars of high surface temperature, since these stars emit a relatively large quantity of radiation capable of disrupting the molecules. Consideration of this problem has shown that for such stars a molecule may persist at distances equal to the capture radius, as given by us for these stars[1], provided the density of material through which the star is passing is sufficiently high. A value 10^{-21} gm. per c.c. for the density can be shown to be adequate for the main body of the O and B stars. In a cloud of this density the life-time against disruption by the action of stellar radiation is of order 10^{13} years. For a cloud of density 10^{-23} gm. per c.c. the life-time of the molecules is much shorter, and in large tracts of the galaxy it may well be the case that molecules are easily dissociated and constitute only a very small fraction of the material in these regions. In this case the temperature of the cloud may be expected to rise to 10,000°, in accordance with Eddington's well-known results.

Accordingly, the reference by Prof. Gamow to the observations of Dunham does not necessarily provide evidence of the temperature in the regions of high hydrogen density, since the interstellar calcium and sodium may be as abundant in regions of low hydrogen density as in regions of high hydrogen density, and the interstellar lines of these elements could then be broadened as a result of high thermal temperature in the regions of low hydrogen density.

Rust-Resistant Wheats for India

All the three rusts of wheat occur in India. It has been shown that in the plains of India the severe summer heat kills the rust spores and that the wheat crop is infected anew each season by spores blown down from the hills, where wheat is cultivated up to an altitude of about 9,000 ft. above sea-level. The barberry, though common in the hills, seems to play little part in the annual recurrence of black rust[1], and it is the self-sown wheat plants and ratoon tillers from harvested plants in the hilly areas which constitute the most obvious means of carry-over of rusts from year to year.

Since 1935, we have been endeavouring to breed rust-resistant wheats suitable for cultivation in the hilly regions of India, the project being financed by the Imperial Council of Agricultural Research. The greatest obstacle in the way of breeding a rust-resistant wheat has been the total lack of *vulgare* varieties highly resistant to the physiological races of black rust occurring in India. Although the number of physiological races is very small (up to date only six races of black rust, six of brown and nine of yellow have been found in this country), no *vulgare* variety resistant to the most virulent and widespread race 15 or race 40 of black rust was available.

The only wheat then known to possess considerable resistance to these races was the *dicoccum* variety, Khapli. Unfortunately crosses between this and *vulgare* varieties either failed or gave rise to sterile plants only. In only one cross (Reliance × Khapli) did an F_1 plant set grains, and even in this case only two grains were obtained. These two grains gave rise to plants of the Khapli type, and subsequent progenies behaved similarly. In view of this difficulty, a thorough search was instituted for *vulgare* varieties resistant to black rust, and each year a large number of indigenous and imported varieties were tested. We are glad to announce that our search has been successful and that in a batch of *vulgare* varieties, most of them bred at Njoro, kindly supplied by the Director of Agriculture, Kenya, a promising degree of resistance has been found. One of them, *E*. 144, has proved to be highly resistant to races 15 and 40.

It will be seen that in *E*. 144 we have a wheat which should greatly simplify the plant breeder's problem in India so far as black rust is concerned. *E*. 144 has also shown marked resistance to a mixture of all the six races of black rust in the adult stage. *E*. 148 is highly resistant to all the races of yellow rust in the seedling stage.

The varieties are late and under Indian conditions poor in yield and, therefore, unsuitable for direct cultivation. They are, however, invaluable for breeding, and we have already made crosses between these and some of the Indian varieties.

A number of Kenya wheats received through the kindness of Dr. H. Wenholz of New South Wales are also under test. These wheats appear to be different from the foregoing, but also include forms which possess high resistance to rust.

Plasma Alkali Reserve in the Domestic Fowl

Experiments have been made in this laboratory with the view of tracing the possible influence of egg production on plasma alkali reserve in the domestic fowl. White Wyandotte pullets were fed on a ration supplemented with 5 per cent calcium carbonate, and others on the same ration without this supplement. The plasma alkali reserve (determined by the Van Slyke–Cullen technique) of the birds on the low calcium ration fell slightly at the start, and then remained at a level between 58 and 66 vol. carbon dioxide per cent; the onset of laying did not have any noticeable effect on plasma alkali reserve.

In the case of the pullets on the high calcium ration the plasma alkali reserve rose during the pre-laying period to a level as high as 88 – 89 vol. carbon dioxide per cent. The values remained high during the laying period, but there were indications that heavy laying may affect the level.

These results were clearly due to female reproductive activity, for the plasma alkali reserve of a cock did not vary outside the limits of 62–69 vol. carbon dioxide per cent whichever ration was fed.

Data for the blood composition of laying and non-laying fowl published by Heller and Pursell[1] also suggest a displacement of blood acid-base equilibrium towards the alkaline side in association with laying: in every instance the blood chloride index calculated from their data is lower in the case of laying birds. These observations are of interest in relation to the changes which egg-laying may bring about in the composition of the fowl's skeleton[2] and to Tyler's[3] recent work on the mineral metabolism of bone in the laying fowl.

Pullets receiving rations adequate in calcium carbonate not infrequently display an unexpectedly high Ca/P retention ratio during the pre-laying period[4,5], suggesting that pre-laying storage of calcium can be in forms with a Ca/P ratio higher than that of the skeleton as a whole. Tyler[3] has recently shown that subsequent drafts on skeletal calcium for shell formation fall preferentially on a bone mineral fraction of very high Ca/P ratio, or may withdraw calcium from the skeleton without withdrawal of phosphorus.

It is suggested that, when the calcium carbonate intake is sufficient, laying is preceded by an adjustment of the blood acid-base equilibrium in association with calcium storage, so that the newly deposited bone mineral may have a higher Ca/P ratio than the skeleton as a whole ; this material would presumably be readily available for shell formation. Morgulis[6] has remarked that the carbonate content of bone (and hence its Ca/P ratio) may be related to blood alkali reserve.

The mineral metabolism of birds laying on low calcium rations requires special consideration and may differ from that of birds receiving adequate calcium supplements. It may be significant that serum phosphatase attains very high levels under such conditions[7].

It is hoped to publish a fuller account of these experiments at a future date.

Co-existence of Oxidizing and Protective Mechanisms for Vitamin C in Plant Tissues

VITAMIN C occurs exclusively in the reduced state in fresh vegetables. Although enzymes and copper, which oxidize the vitamin, are widely distributed in plants, the vitamin is not oxidized. It would appear, therefore, that there must be some mechanism in plants which prevents the oxidation of the vitamin. Although the existence of such protective mechanism has been established in animal tissues[1], it has not been shown to be of such wide occurrence in plants.

During the course of researches on the nature of ascorbic acid oxidase of vegetables, an interesting observation was made on the existence of a protective mechanism in plants, which protects vitamin C against oxidation. It appears that both the enzyme 'ascorbic acid oxidase' and the protective factor occur together in certain vegetables, and the two factors have been separated from one another.

The procedure adopted in obtaining these two factors separately was to add an equal volume of acetone to the expressed juice obtained from the vegetable, and the precipitate which contained the enzyme was centrifuged and dispersed in water. The acetone extract after centrifugation was evaporated on a water bath in order to drive off the acetone completely and the aqueous extract thus obtained contained the protective factor, which protects vitamin C from oxidation, both in presence and absence of added copper. The course of oxidation was followed manometrically by measuring the oxygen uptake in Warburg respirometers, and by titration with the indophenol dye. These two factors are found to exist together in a number of vegetables investigated, and they can be separated by adopting the above procedure. Some of the typical plants which are found to contain these two factors are *Cucumis sativus*, *Cucurbita maxima* and *Luffa acutangula*.

So far there appears to be no indication in the literature regarding the co-existence of both the factors—the oxidizing and the protective factors—in plants. It is probable that the effect of the enzyme ascorbic acid oxidase present in plants outweighs the action of the protective constituents, so that the influence of the latter on vitamin C is not apparent, when both of them occur together. Hence it would appear that the failure of previous workers to observe any significant amount of protective substances in plants is to be ascribed to the occurrence of ascorbic acid oxidase in association with the protective substances, and without separating the enzyme from the protective constituents, the detection of the latter would not be possible.

Further work on the isolation, purification and the nature of the protective constituents is in progress. Full details of the work will be published elsewhere.

Potassium and Carbohydrate Metabolism

Pulver and Verzár[1] have recently reported that the up-take of glucose by the yeast cell is accompanied by a simultaneous up-take of potassium, and that the latter is liberated again in the course of fermentation. It appears to me that this result has some bearing on the interpretation of certain other findings concerning the relation of potassium to carbohydrate metabolism.

It has been found that the anaerobic fermentation of glucose by baker's yeast increased, on an average, by about 150 per cent if potassium (0·01 *M* potassium chloride) was added to the medium, which contained as other cations hydrogen, ammonium and magnesium[2]. An increase occurred also if an equivalent amount of sodium was added, but it was much smaller. Other investigations have shown that the anaerobic fermentation of glucose by tumour tissue was markedly greater in a medium containing both sodium and potassium (in physiological concentrations) than in a medium containing sodium alone[3,4]. Similar results were obtained with normal tissue, especially brain cortex[4]. Further, it was found that the aerobic fermentation and oxidation of glucose by brain cortex could be increased considerably by the addition of a surplus of potassium to the medium[5,6].

These results have shown that potassium is able to activate the enzymatic breakdown of glucose, but the question was left open how this activation takes place. Pulver and Verzár assume that the inward diffusion of potassium which they have observed is connected with the phosphorylation of glucose as the initial reaction leading to the formation of a polysaccharide which afterwards breaks down. This assumption is supported by the result that substances which retard phosphorylation inhibit the uptake of both glucose and potassium. From this point of view there appear to be at present two main possibilities regarding the explanation of the effect of potassium upon fermentation and oxidation of glucose. Either potassium activates phosphorylation, and thereby the subsequent formation of the supposed polysaccharide, or it activates the breakdown of the latter. In the former case potassium might be bound chemically, while in the latter case it might be adsorbed by the polysaccharide (having probably colloidal properties). In both cases potassium would be liberated again as soon as this compound breaks down.

It must remain for the future to ascertain which of these two possibilities agrees with experimental facts, and to find out the detailed mechanism of the potassium effect for yeast cells as well as animal cells.

Advantages of Uranium Fixation in Modern Cytological Technique

An attempt to use uranium as a fixing agent was apparently made as early as 1882 when Schenk[1] noticed that uranium acetate had a mild fixing action and a high degree of penetration. The nitrate and acetate have since been used for special purposes by Cajal[2], Nebel[3] and others. Uranic acid as a substitute for osmic acid was introduced in this laboratory some years ago. Catcheside[4], who kindly carried out a number of tests with this reagent, finally came to the conclusion that, although good fixation could be obtained, the effects were rather erratic, and La Cour[5] later confirmed the views expressed by Catcheside. Semmens[6] first gave a systematic account of the value of uranium as a substitute for osmium in fixatives employed for plant cytology; he also indicated the theoretical grounds for the use of this metal. In a later paper[7] he further pointed out that the erratic fixation previously recorded appeared to be due to the variable composition of the so-called uranic acid of commerce. To overcome this difficulty he proposed the use of sodium diuranate ($Na_2U_2O_7$), a compound that is much easier to standardize.

There has been a marked tendency in recent years towards the use of more simple mixtures than those previously employed for fixing purposes. It may be as well to point out here that simple fixatives will leave the situation much less obscure for those who wish to attempt a biochemical interpretation of cytological results. Extensive trials with numerous types of plant material in this laboratory have led to the decision that Levitsky's[8] chrom-formalin, used for root-tips, gives fixation every bit as good as anything obtained with the more complicated mixtures which include osmic acid. Chrom-formalin, however, does not give such good results with pollen mother cells or with pollen grain divisions, for which the Flemming type of fixative is as a rule more satisfactory. It is a matter of common experience that osmic acid, owing to its high cost, cannot be used for smear preparations made on an extensive scale. For pollen grain divisions and for meiotic material it has been found that sodium diuranate can be very advantageously used in place of osmium tetroxide. 1 per cent chromic acid in which is dissolved 2 per cent of uranium diuranate is now considered to be the most effective mixture and has been used in this laboratory with excellent results.

In the development of the rapid smear methods[9] involving the use of Feulgen light green technique[10], we have tried various combinations of fixing fluids, and as a result of such trials have found that the chrom-uranate mixture not only gives uniform and satisfactory fixation of pollen grains and pollen mother cells but also considerably improves the nucleolar staining, possibly due to the additional mordanting action of the sodium component. It has also been found that this mixture, followed by Newton's gentian violet technique with subsequent chromic mordanting, gives far better preparations which are also more permanent than those obtained by the ordinary method. We therefore strongly recommend the use of sodium diuranate in place of osmium tetroxide in fixing fluids for material that is to be stained by either the Feulgen light green or the gentian violet techniques.

Books and Periodicals for Interned Scientific Men

The Government's policy with regard to aliens has resulted in the internment of a very large proportion of the refugee scientists who were in Great Britain. It should be remembered, as has been recently pointed out by the Prime Minister, that though there may be enemies of the country among them, by far the majority are genuine victims of Fascism and amongst its bitterest opponents. Many refugees have made valuable contributions to science whilst in Great Britain, and some of them were actually engaged in work of national importance at the time of their detention.

We are not able to judge the wisdom or value of this indiscriminating internment, but there is one way by which we can lighten the misfortunes of our fellow scientists and mitigate any feeling of bitterness which might arise. This is by supplying them with the books and periodicals which will enable them to keep abreast of new developments in science and play their part efficiently in the reconstruction of the post-War world.

Those in internment camps are only allowed to receive new books and publications direct from the publishing offices, and individuals could arrange for books to be bought and sent to scientists in the camps. Newly published books and periodicals can also be sent to the camp libraries, and learned societies might consider sending copies of their journals to these libraries through the Y.M.C.A.

Such action would be a valuable demonstration of that international spirit of science on which all true scientists set so much store for the future of humanity.

RESEARCH ITEMS

Prehistoric Village Site, Ontario

THE Lawson prehistoric village site, Middlesex County, Ontario, Canada, had already suffered severely from amateur collectors when it was explored by W. J. Wintemberg during 1921–23, but with the addition of scientifically valuable evidence from private collections it has been possible to reconstruct a picture of the material culture of the inhabitants (*Bull.* 94, Anthrop. Series, 25, Nat. Mus. Canada; 1940). The territory in which the fort is situated is known to have been inhabited by the Neutral Indians of Iroquoian linguistic stock. Probably it had been inhabited long before traders penetrated the region. The site is surrounded by slopes steep on north and south sides, elsewhere less steep. The village probably lay at the east end. Along the north side flows the Medway, a navigable stream, and on the south, Snake Creek, and there is a spring on the west end of the site. Refuse deposits and pits, in groups, of unknown purpose have been found; and there are eleven fireplaces, some round, others oval. The site is strategically important. The east and west ends alone were vulnerable and had to be protected by earthworks. Post-holes for palisades were found along the north and south sides of the site, in places in four rows. The houses were probably like the bark-covered cabins of the Hurons, 2–40 fathoms long and about 4 fathoms wide, and of the same height. Post-holes of small, nearly round habitations, 8–9 ft. in diameter, were found. In the evidence of foodstuffs, animal remains were more numerous than plant remains, but probably both were used in about equal amounts. About 11,000 animal bones were found, including those of mammals, birds, turtles and amphibians, as well as shells of land and freshwater molluscs. About one hundred fish bones were secured. Certain artefacts, animal bones and vegetable products indicate hunting, fishing and agriculture as modes of subsistence. About 14,000 potsherds were found, none, however, permitting reconstruction. Tools consisted of axes, adzes and chisels of stone, antler and teeth, whetstones, rubbers, scrapers, flaking tools, points and hammerstones.

Rock Engravings on the Indus

A SERIES of rock-engravings or chippings were observed in 1931 and succeeding years by Cuthbert King in Attock, the most northerly district of the Punjab Province, India (*Man*, May, 1940). The engravings are on groups of large stones lying on the right (North-West Frontier Province) bank of the Indus about three miles below the Attock bridge near the village of Darwaza. At times of flood and generally during the summer months the rocks are wholly or partially submerged. The stones are of black basalt, and the pictures or marks are pecked on a smooth surface, but not artificially prepared. Local tradition is that the three engraved rocks figured were originally one, which was split by lightning. They certainly show signs of violent fracture, while the technique and subject-matter of the engraving on all three appear uniform in every way. Afterwards, further examples were discovered up-stream, while similar engravings were recorded on rocks near the Haro River about a mile above its junction with the Indus, 1½ miles below the first discovery, and also in the Indus itself above this confluence, but showing slight differences from the Darwaza engravings. Some of the markings show resemblance to Chinese characters, while others resemble stylized figures of Swedish and Spanish rock-engravings. Sir John Marshall, to whom the find was reported, considered them to be of the late historic period, while their similarity to many rock-drawings of the medieval period has been pointed out.

Precautions against American Foul Brood in Bees

CERTAIN aspects in the treatment of American foul brood among bees are discussed in the *Bee World* of June. As in any disease of bees, it is necessary to prevent the bees from carrying infection into a clean hive and also to realize that all infected hives and apparatus require adequate sterilization. If either of these measures be neglected or inadequately carried out, all effort is wasted. Ignorance of the means of infection by a given disease is a potent source of trouble. Thus, until the discovery that *Bacillus pluton* is carried on the mouth-parts of the adult bees, the failure of the most careful measures for controlling American foul brood remained unexplained. In connexion with disinfecting hives, nearly all competent advisors recommend scorching by means of a painter's blow-lamp. This method has its disadvantages, since it is difficult to burn out the corners and crannies without undue burning of the wood. The application of hot washing soda and water is much easier and cheaper to use, but the question arises as to whether it will kill the spores of the disease organism. Apparently a reliable answer to this question is not available and full inquiry is badly needed.

Indian Palæobotany

INDIA has long been known to be very rich in fossil plants, and it is fortunate that there should now be an able Indian palæobotanist with a vigorous school of fellow workers. In a reprinted lecture by B. Sahni ("Recent Advances in Indian Palæobotany", Lucknow University Studies; 1938–39) we have an excellent survey of a field wide enough to include such matters as mountain uplift and continental drift, and in addition a most encouraging promise of fresh results from many pieces of work now in progress. Two of these pieces of work have now appeared ("Jurassic Plants from Afghan Turkistan", by R. V. Sitholey, *Mem. Geol. Surv. Ind.* (*Pal. Indica*), 29, Mem. 1; 1940: "The Fossil Charophyta of the Deccan Inter-trappeans near Rajahmundry (India)", by K. S. Rao and S. R. N. Rao, *ibid.*, Mem. 2); that on the Charophyta provides welcome evidence for the Lower Tertiary rather than Cretaceous age of a very important formation, while Sitholey's work is of value in providing new localities for certain Middle Jurassic species, and though his flora is small, it will be a useful item of information in building up the complicated story of the history of this vast area.

Preservation of Vegetables by Waxing

IT has long been known that a thin film of natural or artificial wax on the surface of plant tissue is effective in reducing its rate of water loss, and commercial processes have been developed, particularly in the citrus industry, which take advantage of this fact, more than 75 per cent of the oranges grown in California and Florida now being treated in this way. The possibility of extending the process to include vegetables which have to be stored for some time before sale is now being investigated and useful results are described by H. Platenius (Cornell Univ. Agric. Exp. Station, N. York, *Bull.* 723). The method which appears to be the most promising is the dipping process, which can be carried out by hand or mechanical equipment. The vegetables are first washed, and without drying are dipped momentarily into a cold wax emulsion at room temperature and then dried thoroughly, the average thickness of the resulting dry film varying from one to two microns. The chemical nature of these emulsions is very complex. Essentially they consist of colloidal suspensions of one or several kinds of waxes in water, the minute particles being kept in the disperse phase by means of a soap. One of the waxes used contained bentonite in addition to paraffin and a soap. Proprietary articles were used in these experiments, and their names, together with those of their manufacturers and partial compositions, are given. A large variety of vegetables were tested. The results obtained with topped carrots and cucumbers were outstandingly good, and in general the process can be recommended for all root crops with the exception of parsnip. The waxing of leafy vegetables is not advised, nor for those which are shipped with ice on top of the container. Waxing does not improve the quality of an inferior product, nor does it prevent the progress of disease; but it does reduce shrinking and maintain the fruit or vegetable in a fresh condition for a longer period than would be possible without treatment.

Rust Fungi of the Genus Prospodium

THE very numerous species of rust fungi form a rather unwieldy taxonomic unit, and it becomes a matter of necessity to sub-divide the Uredinales into convenient sub-groups. One of these, the genus Prospodium, proposed by J. C. Arthur in 1907, has recently been studied in detail by George B. Cummins (*Lloydia*, 3, No. 1, 1–78; The Lloyd Library and Museum, Cincinnati, Ohio, U.S.A., March 1940). Prospodium is separated from the other Uredinales by the picturesque character of possession of appendages to the spore pedicels. This ornate feature is, however, linked to a more fundamental criterion in the limitation of the host range favoured by the genus to Verbenaceæ and Bignoniaceæ. The present discussion attains monographic proportions, with accounts of structure, life-history, taxonomy, a key to the fifty species with a detailed description of each, and the necessary bibliography.

Pleiotropic Effect of Genes

WHETHER genes in general affect only one or a few characters of the organism or whether all genes of an organism affect most characters is an important question in genetics. J. J. Schwab (*Genetics*, 25, 157–178; 1940) has analysed the effect on the shape of the spermatheca of *Drosophila melanogaster* of eleven single mutant strains chosen for convenience of observation. These stocks were continuously backcrossed to an isogenic wild strain and the spermatheca were measured before, during and after the period of backcrossing. Statistical analysis of forty controlled generations, of which twenty were designed to permit crossing-over, was made. It was found that out of eleven segments studied, nine were able to affect the shape of the spermatheca, a character also selected for experimental convenience. Hence "structures may be affected by a multiplicity of genes".

A Fungicidal Fertilizer

S. C. TENG makes the interesting suggestion in *Sinensia* (8, Nos. 5–6; September 1937) that urine be employed as a fungicide, and shows that it is effective against the sclerotinia disease of asparagus lettuce and other maladies. Ammonia is evidently the fungicidal compound, and the liquid is applied during transplantation, at the rate of one litre per square foot of soil. Urine is a common fertilizer in China, and its use as a fungicide in no way diminishes that property.

Constituents of the Higher Fungi

ERGOSTEROL has been isolated from some higher fungi, but so far as was known no well-characterized members of the terpene group, such as the triterpene resinols, had been isolated from fungi. L. C. Cross, C. G. Eliot, I. M. Heilbron and E. R. H. Jones (*J. Chem. Soc.*, 632; 1940) have now examined the birch tree fungus, *Polyporus betulinus* Fr., and after saponification of the extracts have isolated three polyporenic acids, all of which are probably triterpenoid. Two of these (*A* and *B*) appear to be isomeric $C_{30}H_{48}O_4$ acids, and both contain two hydroxyl groups and two ethylenic linkages. The third (*C*) may be identical with gypsogenin, $C_{30}H_{46}O_4$, isolated from Gypsophila and other species of Saponaria.

Earthquakes in the Aleutian Islands

THE United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the epicentres of the earthquakes of April 16 and May 4, 1940. The shock of April 16 happened at 6h. 7·7m. G.C.T., and, using reports from twenty-six seismograph stations, the epicentre was calculated to be near lat. 52·6° N., long. 173·8° E., which is just to the north-east of Near Island at the extreme western end of the Aleutian Islands. The shock of May 4 occurred at 7h. 24·1m. G.C.T., and from instrumental reports obtained from Weston, Honolulu, Hong Kong, Manila, Sitka, State College (Pa.), Chicago, Fordham College (Alaska) and Burlington the epicentre turned out to be very close to the previous one, namely, lat. 53·0° N., long. 173·0° E., or immediately north of the Island of Attu at the extreme western end of the Aleutian Islands group. Increased seismic activity in the Aleutian Islands has been noticeable during recent months.

Structure of Sulphur Dioxide

THE structure of the sulphur dioxide molecule has been re-investigated by the electron diffraction method by V. Schomaker and D. P. Stevenson (*J. Amer.

Chem. Soc., 62, 1270; 1940), who have obtained improved diffraction photographs and find the following results. The S—O distance is 1·43 ± 0·01 A. and the bond angle O—S—O 120 ± 5°. The entropy determination of Giauque and Stephenson (*ibid.*, 60, 1389; 1938) gave for the product of the three principal moments of inertia of the SO_2 molecule the value $(10 \cdot 58 \pm 0 \cdot 99) \times 10^{-116}$ gm.cm.^{2}, and this value with the above bond distance gives 121° as the bond angle, in excellent agreement with the electron diffraction value.

Configurations of Quadricovalent Complexes

As is well known, the configuration of some 4-covalent complex compounds of metals is tetrahedral, and of others it is planar. G. N. Tyson and S. C. Adams (*J. Amer. Chem. Soc.*, 62, 1228; 1940) have measured the magnetic susceptibilities of salicylaldehyde complexes of copper, nickel and cobalt, and the salicylaldimine complexes of copper and nickel. From the results the following configurations have been assigned to the compounds. Cobaltous and nickelous disalicylaldehyde probably have tetrahedral configurations, nickelous disalicylaldimine is planar, and cupric disalicylaldehyde and cupric disalicylaldimine are probably planar. In the case of the nickelous compounds, the formation of the disalicylaldimine from the disalicylaldehyde involves a change from a tetrahedral to a planar configuration, and this is attended by a marked colour change from green to orange.

Attainment of Very High Pressures

M. JAMES BASSETT has recently described the attainment of pressures of the order 50–75,000 kilograms per sq. cm. (*J. de Phys. et le Radium*, Ser. 8, 1; April 1940). This has been achieved by the use of a special carbide of tungsten, out of which the component parts have largely been made, though steel forms part of the general framework. A special feature of the apparatus is its maintenance at the temperature of liquid air, thus taking advantage of the increased resistance to compression or tension which all metallic bodies exhibit at low temperatures; special precautions are taken to prevent any access or accumulation of moisture. Three diagrams illustrate the main features of the design, but the scale of operations which could be carried out cannot be stated, as no dimensions are given in the text.

Photographic Action of Metals

THE photographic action of certain metals has been fully recognized since the researches of Russell more than forty years ago. J. A. Reboul returns to this subject (*J. de Phys. et le Radium*, Ser. 8, 1; 1940). Further experiments have led him to the view that Russell's working hypothesis is inadequate to account for all of the phenomena which have been observed to date. Russell maintained that the action was due to the presence of hydrogen peroxide. This is allowed by Reboul, who, however, maintains that part of the effect is due to a very 'soft' radiation from the metals themselves; he hazards the view that this radiation is itself excited by cosmic radiation. Such a conclusion is tentative in view of the fact that these phenomena have so far not been examined under conditions which, of themselves, reduce the cosmic radiation to insignificant proportions. The protean character of the phenomena remind the reader of the Volta effect.

The *K* Term and the Galactic Rotational Constant

W. M. SMART has criticized the claims of Plaskett and Pearce to have solved the mystery of the *K* term (*Mon. Not. Roy. Astro. Soc.*, 100, 5; March 1940). Some time ago, Smart offered some criticisms of their work (*Mon. Not. Roy. Astro. Soc.*, 96, 568) and Plaskett accepted the validity of the criticism; but in spite of this, he still maintains that in actual practice a theoretically incorrect procedure is justified by the results. In their investigations, Plaskett and Pearce made use of 132 *B*-type stars lying between galactic longitudes 210° and 330°, known as the Southern Stream, which they believed formed a moving cluster. Smart has shown (*Mon. Not. Roy. Astro Soc.*, 100, 60) that these stars do not form a moving cluster but are merely a normal sample of *B* stars, yielding a solar motion of 19 km./sec. and a *K* term of 5·2 km./sec. The value of $K = 8 \cdot 3$, derived from the stars of this so-called Southern Stream, has very little significance. He now shows that in their earlier paper Plaskett and Pearce gave solutions which were derived from an incomplete equation of condition and are therefore erroneous. The conclusion is that the only information relating to the *K* term of moderate accuracy that survives concerns the normality of the *K* term for the distant stars of Groups 1 and 2. It is impossible to say at present what the value of *K* will be for the nearer stars, included in Groups 3 and 4; this can be obtained when solutions are made for these groups with the corrected equation of condition and without any arbitrary adjustment of the radial velocities. The claim of Plaskett and Pearce to have reduced the *K* term to its gravitational value is not admitted.

Masses of the Stars

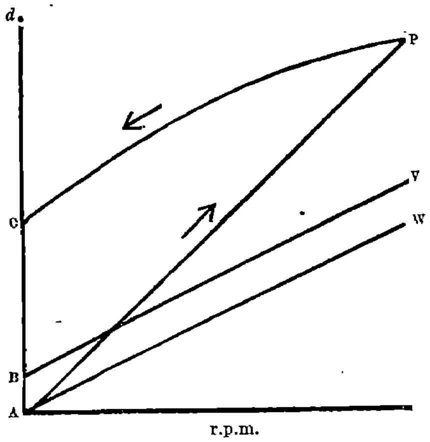
A MONOGRAPH with this title, by Henry Norris Russell and Charlotte E. Moore, has appeared (Chicago: University of Chicago Press. London: Cambridge University Press. 21*s*. net). It is the outcome of a lecture delivered by Prof. Russell in connexion with the Harvard tercentenary and contains all the direct evidence available regarding the masses of the stars, that is, that derived by gravitational motions from binary systems. The first chapter deals with visual binaries and contains a large amount of statistical discussions. A new empirical formula connecting mass with luminosity is given at the end of the chapter, and though it is impossible to provide a complete theoretical explanation of the formula, nevertheless it is available over a wide range, and should be adequate for the computation of stellar parallaxes. Spectroscopic and visual binaries are dealt with in the second chapter, and in the next chapter there is a collection of various discussions under the headings, statistical theory for slow-moving pairs, triple systems, mass ratios, astrophysical conclusions. A curve shows the close agreement between the empirical linear formula connecting mass and luminosity and observational data, and where large discordances exist these correspond to small or poorly determined groups, or to uncertainty in the individual values, as in the case of the "Trumpler stars". Chapter iv presents a new treatment of the determination of dynamical parallaxes and introduces a number of refinements. Tables are also given which facilitate the computation of parallaxes from double-star data. In the last chapter there is a general catalogue of the dynamical parallaxes of 2,529 stars which have been calculated by the methods explained in the previous chapter.

RELATIONS BETWEEN MOLECULAR AND MORPHOLOGICAL SHAPE OF PROTEIN SOLUTIONS

By DR. A. S. C. LAWRENCE, DR. JOSEPH NEEDHAM AND DR. SHIH-CHANG SHEN,
UNIVERSITY OF CAMBRIDGE

THE experiments on which we wish to make the following preliminary report originated from our belief that further knowledge of the shapes of molecules may throw light on the nature of morphological and histological shapes, and the changes which they undergo. We were especially interested in the formation of the neural tube in the amphibian embryo, where this, the first, morphological change in development consists of a great lengthening of the cuboidal ectodermal cells and nuclei to form the cells of the neural plate. The question arises whether this elongation may not depend upon, or be accompanied by, an increase in the number, size, or axial ratio of anisometric protein particles present. With this in mind, we compared the behaviour of protein fractions isolated from amphibian neurulæ with that of other proteins.

The viscosimeter, designed by one of us (A.S.C.L.), consists of an inner cylinder of stainless steel suspended on a torsion wire, and an outer cylinder of stainless steel which can be evenly rotated at speeds varying from 0·5 to 200 revolutions per min., the whole being contained in a jacket allowing of accurate temperature control. The apparatus allows also of simultaneous measurement of flow birefringence. The annular space contains about 15 c.c. when the inner cylinder is just submerged.



The advantages of the Couette (coaxial cylinder) viscosimeter over those of the Ostwald (capillary) viscosimeter are sufficiently well known. The latter gives results from which calculations are scarcely possible since there is no constant rate of shear. Nor is it suitable for studying changes in a solution subjected to known shear forces for varying periods of time. It should also be noted that the study of anomalous flow at low rates of shear is a measure of approximation to complete randomness and hence not interfered with by the simultaneous presence of globular particles, while the study of flow birefringence is interfered with to a much greater extent since it is a measure of approximation to complete orientation in the stream lines.

The results may most conveniently be summarized by reference to the accompanying diagram, which reduces the facts to their simplest form. In the accompanying figure the deflection of the mirror on the torsion wire is plotted against the shear force applied to the solution by the rotation of the outer cylinder. The inner cylinder is not completely submerged. The line *AW* represents that given by water. The line *AP* represents that given by proteins of Class 1. The flow here is normal, and the relative viscosity is therefore constant whatever the shear force. It is to be assumed that proteins of this kind have globular molecules or aggregates. Proteins of Class II, however, give lines such as that shown by *BV*, the reading being abnormally high at low rates of shear and falling off at high rates. Such *anomalous flow* means that the relative viscosity varies with the rate of shear, falling from a very high value to a constant level when perfect orientation of the long particles in the stream lines is attained. On denaturation with guanidine hydrochloride or traces of copper, anomalous flow is completely abolished.

A third class of proteins exhibit more complex behaviour. At first they follow a line similar to that of Class I (*AP*), but when slow speeds are again applied an *anomalous return* is obtained, cutting the abscissa at a much higher level (*PC*). If now this solution is removed from the apparatus, diluted, and put back, anomalous flow, similar to that shown by *BV*, is obtained. It has not as yet been possible to find positive proof that this phenomenon is due to the spinning off of anisometric protein particles from the surface film, but such an explanation appears at present to be the most likely one. That the anomalous return itself is due to the formation of a protein polylayer at the surface on rotation, however, is certain. The formation of such a built-up film, the time-relations of which can be followed in detail, never manifests itself if the inner cylinder is totally submerged, since the torque on the suspension wire is negligible in comparison with that on the cylinder itself.

We have not so far found any protein which showed anomalous flow initially followed by anomalous return.

We are inclined to believe that the initial behaviour of protein solutions of Classes I and III when the inner cylinder is not completely submerged is probably due to a liquid surface monolayer rather than the bulk of the solution, for if the inner cylinder is entirely covered, the concentration of protein needed to obtain equivalent relative viscosities is very greatly increased (for example, from 0·001 to 0·1 per cent). This is not the case, however, in all probability, with proteins of Class II.

We have provisionally placed the proteins studied by us in the following classification :

- Class I. Crystalline methæmoglobin (prep. Dr. Danielli).
  - Crystalline insulin (commercial for physiological use).
- Class III. Crystalline ovo-albumen (prep. Dr. Danielli; many times recrystallized).
  - Myosin (prep. Dr. Bate-Smith. Preparations made in Cambridge, unlike those of Edsall *et al.*[1], show little or no flow birefringence, but appear in all other ways undenatured).
  - Pseudoglobulin from amphibian neurulæ.
  - Aged tobacco-mosaic virus nucleoprotein (which showed less than one-tenth of its original intensity of flow birefringence).
- Class II. Tobacco-mosaic virus nucleoprotein (prep. Dr. Pirie. Here our results are in complete confirmation of those of Robinson[2]).
  - Total globulin fraction from amphibian neurulæ.
  - "Myosin" fraction from amphibian neurulæ.

To the above we should like only to add that we have noted remarkable continuous decreases in relative viscosity of certain protein solutions even when standing at 0° C., notably the amphibian embryo pseudoglobulin fraction. In most of the proteins studied the concentration/viscosity relationship must have the characteristic curves sharply bent between the steep and flat regions, since it is often difficult to hit upon the concentration which will give a relative viscosity in the optimal region for observation.

As regards the embryological significance of our findings, it may be said that they strengthen previous indications (such as those of Miller and Moore[3], Schmidt[4], Needham and Robinson[5], etc.) of the existence of anisometric particles in developing eggs and embryos. Such particles may well be concerned with the shape changes of neural cell formation. The proteins were extracted from embryos frozen at −77° C. and dried *in vacuo* by methods similar to those of Mirsky[6]. Apart from the behaviour of pseudoglobulin, the anomalous flow of the globulin fraction (consisting largely but not entirely of vitellin) invites the question whether vitellin has not been looked upon in the past too exclusively as a nutritive reserve. Yolk-platelets of amphibia were stated long ago by Radlkofer[7] to show weak birefringence. We hope in due course to publish a complete account of the foregoing experiments and to continue the examination of the viscosity of protein solutions both from embryonic and other sources, on which so much remains to be done.

MARINE ECOLOGY AT HULL

INVESTIGATIONS on the ecology of plankton in the North Sea and the relationships between the plankton and the fisheries have been made now for some years at the Department of Zoology and Oceanography at University College, Hull, under the direction of Prof. A. C. Hardy. The results of some of this work have been published elsewhere, but recently Prof. Hardy has started a new periodical for oceanographical investigations undertaken by the Department. This is entitled the *Hull Bulletins of Marine Ecology*, of which Nos. 1 and 2 of vol. 1 appeared in November 1939 and vol. 1, No. 3 in March 1940. The publications to date are concerned with research with the continuous plankton recorder. No. 1, which is by Prof. Hardy, contains an account of the ingenious recording machine and the method of working it, together with a summary of the plan and scope of the survey made with the instrument. A number of collecting lines have been run across the North Sea at regular intervals of time, and No. 2 of the *Hull Bulletins* contains a list of records made from 1932 until 1937.

The idea of the survey is to attempt "to apply methods similar to those employed in meteorology to a study of the changing plankton distribution, its causes and effects". In this respect it has considerable bearing on problems of the economic fisheries, such as the influence of the amount of plankton in any one area and at any one time on the survival of young fish and the movements of shoals of adults. At the same time the collections provide an index of the movements of water masses as indicated by the contained plankton organisms. No. 3, by C. E. Lucas, contains an account of the distribution of the phytoplankton in the southern North Sea in 1932–37 as shown by the continuous recorder. The report is chiefly in the form of data on which comparisons of different years may be based, and interesting differences are already apparent. Any full consideration of the results must, however, naturally await the final working up and correlation of all the material available.

The scheme of research undertaken by Prof. Hardy was ambitious, and he will earn the gratitude of oceanographers for having carried it through with such signal success. The results already published show good prospects that, given the funds and opportunity, the continuous observation of certain aspects of oceanography on meteorological lines is a possibility.

It is most regrettable that the War has brought these observations temporarily to a close, and when times of peace return they should be restarted and extended over even wider areas. The *Hull Bulletins of Marine Ecology* will form an important addition to oceanographical literature: it would be most unfortunate if, as suggested on their cover, they only formed a completed work of one or two volumes. In welcoming the new serial the hope may, therefore, be expressed that in due course it will become a permanent addition to publications devoted to oceanographical research, for in Great Britain the number of such journals is at present far from adequate.

NATIONAL RESEARCH COUNCIL OF CANADA

THE twenty-second annual report of the National Research Council of Canada for the year 1938–39 includes the report of the president, Major-General A. G. L. McNaughton, together with the financial statement printed both in French and in English. The review of activities of the Council has this year been published separately.

The president's report refers briefly to work in the Division of Biology and Agriculture on difficulties experienced in the curing and transport of 'Wiltshire bacon' intended for the British market, as well as to other researches on the storage and transport of food. A report on the comparative malting qualities of nineteen barley varieties grown in Canada has been issued in co-operation with the University of Manitoba, and improved methods of predicting the malting qualities of new barleys have been worked out so that satisfactory results can be obtained from small samples. Much progress has been made with investigations on the practical applications of plant hormones, and a commercial hormone powder is now on the market. Promising results have been obtained in co-operation with the Central Experimental Farm in producing a hardy, large-seeded perennial forage plant for the drought areas by crossing wheat with wheat grasses. A new apparatus has been constructed for the measurement of gas production of fermenting doughs with the view of improving baking practice.

In the Division of Chemistry, which has been reorganized during the year, tests were carried out in regard to the production in Canada of face-pieces for gas masks, as well as on the construction and testing of gas-mask containers and the production of adsorbent charcoal. The investigation of domestic barks as sources of tanning extracts continued, and a thorough study was made of the factors entering into the preparation from skimmed milk of rennet casein of a quality suitable for the manufacture of plastics, particularly buttons. Tests are being carried out on the treatment of casein to render it suitable for high-speed injection moulding. Progress in work on magnesium products in the laboratory has been so marked that payments to Canadian railways for freight on the products from the co-operative companies' plants each year now amount to almost as much as the total sum spent on the investigation since the work commenced more than twelve years ago. Fundamental information regarding plasticizing agents has been successfully applied to several types of acid, basic and neutral refractory cements, which are now being manufactured commercially. Laboratory work on the production of asbestos fibre for filtration purposes has been completed and filtration tests carried out on the material. A satisfactory laboratory method for the synthesis of organic selenides has been developed, and the value of selenium compounds as anti-knock agents for motor fuels is being investigated.

Work on the snow performance of aircraft skis has continued, and the Council participated in a comprehensive investigation of aviation fuels under the auspices of the Society of Automotive Engineers. Much work was done for Government Departments, especially on aircraft instruments for the Department of National Defence. Models of ships for Government service were tested by naval architects in the model testing basin.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

TEACHER OF PRODUCTION ENGINEERING—The Principal, Dolcoath Technical School, Camborne, Cornwall (July 31).

DEMONSTRATOR (male) in the Department of Physiology—The Medical School Secretary, Middlesex Hospital, W.1.

MEN OF SCIENCE AND THE WAR

SINCE the War, and in the months preceding it, it has been repeatedly urged in these columns that the times demand the maximum use of science and the full recognition by men of science of their social responsibilities. A year before the unstable international situation resolved itself into the present disastrous conflict, pages of NATURE were devoted to statements by the scientific leaders of the country about the urgent need for scientific workers to undertake these responsibilities, but little of practical import has resulted so far. If the War succeeds in arousing certain men of science to a realization of the social implications of their work, then it may be said that some good has come out of it, and it is to be hoped that such will be lasting. Men of science are proving invaluable at the present time; may their value still be recognized when the time for reconstruction comes.

With the War, the country implicitly assumed a reorganization so profound that the full realization of its meaning only dawned in most minds after the disasters of Norway, Flanders and France, and with the victorious onrush of the German war-machine. To-day no persuasion is needed to impress on people the necessity for making all possible use of the country's powers and resources. That message rings in our ears daily. But no efforts, however heroic, however widespread, and however energetic, will succeed in their objects without right direction—and such direction demands the full use of science.

The Germans have demonstrated that this is a mechanized and technical war. It is not sufficient therefore for us to have limitless material resources; it is essential to use them in a thoroughly planned and integrated way. Until now (and this is still the case), planning has been the task of our political and industrial leaders and of the Civil Service alone. There is no need for us to dwell on the results of their efforts. As men of science our responsibility to-day is to see that things get done, not to blame others if they have not been done.

The important part that men of science have already played in this War has been amply recognized in these columns. The Scientific and Research Departments of the Services, the Department of Scientific and Industrial Research and its kindred bodies, and the Medical Research Council, fortified as they have been by the addition of many academic men of science, have been fulfilling their appointed duties. But many scientific workers have not been used at all, and others, who have for long been in Government service, or who have been recruited since the War, are not being used to their fullest capacities. The fundamental reason for this (and this is the fundamental defect of the whole organization) is that the functions of science have been generally conceived, to a large extent even by men of science themselves, in altogether too restricted a way. A general scientific point of view is foreign to the direction of the country, and in particular to its administrators. If this defect is to be remedied, men of science themselves must show the way.

On p. 112 of this issue is reviewed a book which deals with this very problem. One of its lessons is that in order to discover what are the urgent problems before us, and to determine their order of importance, it is first necessary to survey the whole field of national resources and national effort. This object will not be successfully achieved by administrative methods alone, and such methods so far constitute the only treatment of this particular question. They can lead no further than to a statement of the most apparent facts, whereas there is little doubt that a scientific approach would often reveal key problems, the solutions of which would advance matters more rapidly, and with less effort than any amount of energy directed along traditional paths. But if we are to achieve the best from a scientific approach to a fundamental survey of the problems before us, it is essential that the man of science should be given effective authority to make comprehensive inquiries, to formulate and to solve problems and, not less, to see that the solutions which he suggests are embodied in practical measures.

The above-mentioned book provides several examples where this approach has already been used successfully (for example, in dealing with the magnetic mine and with war diseases), and it indicates several others where it could be applied with all promise of success (for example, in dealing with the menace of tanks and providing an adequate food supply from domestic sources). It is apparent that the book refers, partly for reasons of space and partly because of the limitations imposed by the need for secrecy, to only a few of the many problems which could be tackled more vigorously than they seem to be at present; and the issues discussed are mainly detailed ones. More general problems are only hinted at, for clearly without the proper general fundamental survey no one is in a position to state them explicitly.

Since May, the circumstances for making full use of science have grown more favourable than ever before in the history of Great Britain. Complacency has given way to an acute appreciation of the fact that we have urgent unfulfilled needs, and failure has shown the inadequacy of traditional methods. Blame has very rightly been laid on administrators and industrial leaders for failing to achieve the desired results; but for us the lesson is rather in the failure of men of science to realize both the power that lies in their hands and their responsibility for using it. Men of science can no longer be complacent about neglect, or content with such notice as merely seeks their advice about particular issues. With few exceptions they have not regarded it as their duty to force on an unscientific administration their reading of the dangers and of the means for counteracting them. They have regarded their functions as served when their advice has been sought and given. It was not for them to see that it was acted upon. As "J. S. H." points out on p. 113, "half the battle in science consists in asking new questions which the non-scientist cannot be expected to think of".

More than this is demanded to-day. "Go to it," in the words of the new Government slogan, applies not only to the factory worker carrying out his routine duties. It applies even more to the scientific worker—demanding of him initiative, organizing ability and drive, and the clear realization that only with the help of these can the forces of reaction and inertia be turned aside, and our war effort rapidly brought to a successful end.

HOURS OF WORK AND EFFICIENCY

DURING the nineteenth century, industrial development was governed by the claims of machinery rather than of man. It was a period of gradually increasing control of the environment through machines; at the same time, the studies made in the natural sciences and the growing knowledge of the mechanism of the body all tended to focus interest on man's likeness to a machine. Being *like* is not, however, equivalent to being *nothing but.*

The phrase "the human machine", which rightly interpreted refers to part of man's structure, became by implication rather than by design synonymous with man himself. The idea is very old, but the actual form of the expression dates from the eighteenth century when La Mettrie published "L'Homme Machine"; he also wrote "L'Homme Plante", but nobody seems to have been interested in man as a plant.

The almost incredible result of this point of view is reflected in the treatment of industrial workers at the beginning of the nineteenth century, when even children worked in the mills for nineteen hours a day. One might indeed argue that human beings were considered inferior to machines, since care was taken to keep the latter fit.

The problem of munition production during the War of 1914–18 challenged the adequacy of this point of view. Industrial operations at the beginning of the period were implicitly based on a misguided application of arithmetic. If one unit of work could be done in one hour, then 2 would be done in 2, 3 in 3, 8 in 8, 10 in 10, 12 in 12. The physiological necessity for sleep limited the indefinite extension of this principle. It was therefore an easy problem to find out how many units would be done in 100 hours by 100 men. The discrepancy between the expected and the observed output led to inquiry, resulting in a change of interest from the machine to the worker of the machine. The Health of Munition Workers' Committee was set up "to consider and advise on questions of industrial fatigue and other matters affecting the personal health and efficiency of workers in munition factories and workshops". The Committee found that "the ordinary restrictions on hours of employment were widely relaxed. Sunday labour, previously forbidden for women and young persons, and practically unknown for men, except for a few continuous processes, became common". Men were employed for 70–90 hours a week as a common occurrence, more than 90 hours were not infrequent, and there were cases of even 100 hours.

After investigation, the Committee reported that the "munition workers in general have been allowed to reach a state of reduced efficiency and lowered health which might have been avoided without reduction of output by attention to the details of daily and weekly rests".

The research work conducted by this Committee into the relationship of output to hours of work is now historical. It is, of course, true that, within certain limits, an increase in the hours of work will increase the output ; more work can be done in five hours than in two hours, but if eight hours work produces eight times as many units of work as one hour, will ten, eleven and twelve produce the equivalent increase ? A study of munition work in the War of 1914–18 showed that, in the long run, it did not.

After the War, a number of trades were studied from this point of view and confirmed the wartime experience that : (1) An extension of the usual hours of work—except for short emergency periods—does not give a proportional increase. (2) After a prolonged period of overtime which has led to reduction in output, a return to the normal number of hours does not result immediately in improvement. In some cases three months were required before normal output was restored.

The using up of too much reserve energy left the worker unable to put out his maximum effort, or rather his maximum effort was much below his previous maximum. The effect of excessive hours does not show itself always or solely in a reduction of quantity ; in some processes the quantity might be maintained but the quality could be affected, or sickness absence might be increased, and just when adequate nourishment was most important, workers would describe themselves as "too tired to eat". These general statements are the expression of a number of statistical surveys and numerous interviews.

A group of people frequently overlooked in discussions on output and hours are the highly skilled individual workers and those holding managerial posts. The reason is that, owing to the nature of their work, it is impossible to obtain statistical evidence. Since it is a hard fact that continuous human activity, whether physical or mental, is associated with diminished success at that activity wherever it has been measured, these workers will, as others, be subject to this diminished success. The well-known work curve, that is, gradually increasing success, followed by stability and then gradually diminishing success, has been shown to be true of various activities both physical and mental. On the mental side, fatigue may show itself as irritability ; should the irritable person be the head of an organization or department, the consequences of his irritability, probably directed against his subordinates, may be very serious. Work demanding close attention, high intelligence always alert, and swift impersonal decisions will be very much affected by the condition resulting from physical and mental fatigue.

The expressions of fatigue, namely, diminished efficiency, weariness and an appearance of listlessness may be present when the work is light and hours normal. This condition is due not to the using up of reserve energy, but to lack of interest due to absence of change. Modern methods of production have tended in a number of processes to reduce the opportunities for relaxation and change. Work becomes monotonous and the worker is bored. The remedy for this condition is change either in the work or in the conditions of the work.

In a letter from the Association of Scientific Workers published in NATURE of June 29, it is stated that scientific staffs have, during the recent emergency, been working the same long hours as the factory workers. One reason for this may well have been psychological. Assuming that an organization employs a considerable number of scientific workers in the same building as the factory workers, it would have been worth while, for the sake of the general morale, to make no difference for the emergency period between the different staffs, even though the extra hours were not so urgently necessary in all departments. It needs little imagination to hear a tired factory worker working a seven-day week and seeing the scientific staff going off as usual express his views of the latter in strong language. It is also possible that, for the emergency period, the extra hours were necessary for all staffs. At the risk of some fatigue, the effort that by general consent was urgently needed at that moment had to be made. In any event, emergencies are not occasions for explanations.

From several of the statements which have been made during the past few weeks, it has been clear that the Minister of Labour, Mr. Ernest Bevin, is fully aware of the possibility of defeating the end by excessive hours. The explanation is probably in the fact, not generally realized, that Mr. Bevin was for several years a member of the Industrial Health Research Board. Relaxation of the original heavy demands were made after a very short interval, and now we have the announcement that the restrictions imposed by the Factory Acts are to be re-imposed next month.

Experimental evidence on the relation of hours of work to mental work is much more difficult to determine, since an adequate standard of comparison is lacking. Where output cannot be measured, indirect measures, never so convincing practically, have to be used. In the industrial world, sickness absence and labour wastage are useful indexes at times. It is rare though that adequate records are kept for those whose work is generally called 'mental'. In two fairly large scientific organizations with sickness records that were strictly comparable, one had a low sickness rate and the other a high one, the reasons being as usual complicated.

Some years ago an experiment was conducted by a scientific worker with the aim of showing the relationship between loss of sleep and mental efficiency. Since the loss of sleep involved working extra hours—merely being awake acquiescing in existence was avoided—the results may be relevant. The mental efficiency was measured by tests involving speed and accuracy of movement, close attention, memory for rational relationships and mechanical memory, for all of which the normal variations had been determined over a period of many weeks. The results of a number of experiments showed that both speed and accuracy were reduced, that the capacity to see relationships was weakened and that memory became increasingly fallible. It also appeared that there was a disproportionate period of reduced efficiency after the loss of sleep had been compensated. This is quite in harmony with the industrial findings using output as a measure. This example may have some bearing on the problem of the intellectual worker, though since it was limited to one person, its results cannot be generalized.

It is perhaps worth noting that fatigue in itself is not bad but has an important and positive function in protecting the organism against its own tendency to excess. As the Health of Munitions Workers' Committee put it: "The true test of an excessive fatigue is its progressive character, so that during normal rest and recreation the effect is not abolished".

Another point to be remembered in all discussions on hours of work, is that most of the general statements that are valid statistically refer to large numbers engaged on the same work, so that the final expression represents the general trend of a group. Where in addition individual output curves are obtained, there is found to be considerable individual variation in the form of output curves.

If organizations employing scientific staffs as well as others arrange their work on the model of routine workers, they run the risk of having routine scientific workers whose initiative and creative ability has been denied expression and who are therefore a loss to the community. Thus while we make no claim on behalf of scientific workers for preferential treatment at a time like the present, it is clear that their reactions, and those of others normally engaged in intellectual, as distinct from manual work, to long-continued and regular increase of hours, are not established, and care must be exercised lest increased hours defeat the purpose in view. Decrease in effectiveness, or of output, will result from undue pressure, whether it is imposed from outside or by the worker himself; and this must be guarded against if the efficiency of our war-effort is to be maintained.

McLENNAN: A PIONEER OF CANADIAN SCIENCE

Sir John Cunningham McLennan

A Memoir. By H. H. Langton. With a Chapter on his Scientific Work by E. F. Burton. Pp. viii + 124 + 13 plates. (Toronto: University of Toronto Press; London: Oxford University Press, 1939.) 11*s.* 6*d.* net.

IT requires a mental effort for the present generation of Englishmen when they see the highly industrialized communities on the other side of the Atlantic to realize how rapidly these have grown up. At a dinner given to the contributors to the eleventh edition of the "Encyclopædia Britannica", there was a printed paper of extracts from the first edition, and the entire article on Canada ran somewhat as follows: "*Canada.* A vast wilderness to the north of the American Colonies." When Sir John McLennan began his career, Canada had indeed made some progress in geology, and perhaps in other branches of natural history—but Canadian physics was practically non-existent. His biography is a valuable contribution to the history of how it came into being, and his work, combined with the work of Callendar and Rutherford at Montreal, is perhaps the most important part of the story.

In this book, we can learn what has scarcely been known in England, the story of his early years and the difficulties he had to overcome to get such training in physics as could then be had in his native country. It is an interesting question how far men with real scientific aptitude can be kept back for want of early opportunity. McLennan, though of course scarcely to be classed with Faraday or Pasteur in achievement, accomplished fine work with little more initial advantage than fell to them. It was when he arrived at the Cavendish Laboratory in 1898 that I first had the privilege of knowing him. His manner had the same quiet impressiveness as later. Not that he, or any of us, were unduly solemn for our years: I remember Rutherford asking if he had brought his scalping knife with him.

We were all impressed in those early days with McLennan's dogged tenacity in the rather difficult piece of work assigned to him. This book brings out what great energy he put into everything he set his hand to. It is interesting to learn that he sometimes had regrets that he had not found his way into politics. He might well have succeeded in it, for he was at least as much at home in dealing with men as in struggling with physical apparatus. In particular, McLennan had genuine interest in, and friendship for, young people, and at once established the right relation with them. No doubt this was a great factor in his success in building up the School of Physics in Toronto.

His best scientific work was his identification of the origin of the green auroral line. This and other parts of his scientific work are relegated for the most part to an appendix by his successor, Prof. E. F. Burton. I think, however, that it is a pity that this subject was not treated more freely and fully. The way that this line appears bright and apparently isolated when the aurora is examined in a pocket spectroscope, while at the same time not a trace of it can be seen in the spectrum of any of the atmospheric gases, or of air itself as ordinarily observed, formed a most stimulating mystery, far more intriguing than the artificial mysteries of detective stories. It had puzzled two generations of physicists. McLennan solved it, and this by itself ensures that his name will not be forgotten.

The work that was done in the Toronto laboratory was nearly all published by McLennan jointly with younger authors. He explained to me that he was only too glad to let them work out their own problems in their own way and publish independently if they were able; but he found that they nearly always came to him for guidance as to what they should do, and how they should do it. He sat up late night after night reading contemporary papers from the literature, to get suggestions for the work to be done, and the burden of this, on the top of teaching and administrative duties, became very heavy as the years went on. In the early days of his retirement, he appreciated the relief of discontinuing it. But his retiring years were clouded by domestic anxiety and bereavement. He bore up bravely, and as well as he was able. But he said that things no longer seemed worth while.

It is a matter of satisfaction that a connected account of his career should now be available. We could have wished that more of his talk, his methods of work, and his reaction to things and people could have found a place in the record. Kindly though he was to his friends, he was not averse to explaining how he had got the better of anyone who opposed or obstructed him. But it is regrettably seldom that anything of that kind finds its way into a biography. The difficulty is that for so long as such things are fresh in living memories which can relate them, there are the susceptibilities of living people to be considered.

RAYLEIGH.

SCIENCE IN WAR

Science in War
(Penguin Special, S. 74.) Pp. 140. (Harmondsworth: Penguin Books, 1940.) 6*d.*

THIS is a tract for the times, which every scientific worker should read. There will often be disagreement with the views advanced, but it is eminently desirable that they should be aired. The main thesis of the book is that Great Britain has not learned the scientific lesson of the war of 1914–18 nearly so well as Germany, and that part of the responsibility for this state of affairs lies at the door of men of science themselves.

The real scientific lesson of 1914–18 was not that science should be more liberally employed by this or that department for particular problems, but that a scientific approach is needed to the problem of war in its entirety.

This book, which is by twenty-five anonymous scientific authors, begins by reminding its readers of some of the successful applications of science to war in the past: Haber's nitrogen process making it possible for Germany to survive for four years in the last war, Bergius' oil-from-coal process providing Germany in this war with a respectable fraction of her petrol needs, the success of aerodynamic research, the virtual abolition of typhoid and paratyphoid among armies in the field, the prompt countering of the magnetic mine by the de-gaussing girdle, and so on.

But the bulk of the volume is concerned with suggestions as to the ways in which science could render more aid in this war. It is recognized that in certain fields, such as blood transfusion, aerodynamics, or the physiology of high-speed flying, the scientific situation is excellent. But elsewhere it is not. A leading article in NATURE of June 22, p. 949, is quoted to show that the question of camouflage is being fumbled: the underlying scientific principles are not being applied, and the direction of the work is being entrusted to artists and Civil Servants instead of to the scientific experts. The new types of wounds, such as splinter-wounds, and recent discoveries in the physiology of growth and regeneration call for better co-ordination and larger scale work in relation to wound treatment. Endocrine research might be devoted to the problem of inducing more rapid growth in livestock. The large wastes in various crops which arise from our inefficient methods of seed-production could be markedly reduced by proper organization, once the underlying scientific principles are grasped. The utilization of miniature methods of radiography would enable every recruit for the services or for industry to be X-rayed as a simple matter of routine, so permitting the diagnosis of early tuberculosis, reducing wastage of man-power, and improving national health. In the building of factories, considerable waste of steel is taking place through a neglect of scientific principles of design and the frequent employment of spans much in excess of what is needed. In purely military affairs, it is claimed that a scientifically conducted survey of the anti-tank measures adopted in the Spanish War would have enabled us to prophesy the comparative uselessness of our anti-tank guns, and would long ago have indicated the lines along which successful weapons are to be found.

These are a few of the specific examples which the anonymous authors adduce. In other cases, what is lacking is not so much specific research or scientific application as a general scientific approach. This is well illustrated by the chapter on food. It was only after nine months of war that the scientific advisory committee on national food requirements was appointed (NATURE, June 8, p. 887). Policy up till then had been a compromise between tradition, specific scientific advice, the views of the National Farmers' Union, and various interests concerned with food production and food marketing. The agricultural advisory services and research institutes were scarcely used to advise on the ploughing-up scheme. A lead is still lacking as to the amount and type of fertilizers required for maximum production. Only half-hearted attempts have been made to ensure maximum human efficiency by seeing that everyone gets enough protective food substances (it is stated that a 'vitamin biscuit' giving adequate amounts of the ten most important vitamins and the three or four essential mineral salts could be provided daily for every man, woman and child at a cost much less than, for example, the pre-war sugar beet subsidy).

The man of science sees the problem as a two-fold one: first, to ensure a national diet adequate for full physiological health, and secondly, to save as much shipping space as possible by substituting home production for importation. There may, of course, be cases where economic foreign policy demands that certain imports be retained, where certain types of boats (for example, banana boats) cannot be converted to other uses, where to cut down drastically on certain foods (for example, meat) would be bad for morale; but these involve merely adjustments of the main principle. Once such a unified approach is agreed upon, sectional interests and traditional inertia must and can be overcome.

However, a still more general approach is possible. What is needed is the recognition that the world we live in is a technological world, and that success in it therefore depends primarily upon the utilization of scientific knowledge and of scientific method. This is just as true of war as of peace, of human affairs as of engineering or bacteriology. Scientific management is as necessary as, say, chemical warfare research. But the main need is the integration of all aspects of the war—strategy and tactics, supply and food, propaganda and morale—in a comprehensive scheme of scientific planning with proper facilities and proper co-ordination.

Traditionalism is one enemy of technical efficiency. Tradition may be extremely valuable: it becomes dangerous when the assertion is made that it *must* be valuable. Another enemy is the ignorance and sometimes mistrust of science still to be found in many important quarters—in business, farming, the Civil Service, among military authorities. This has expressed itself very frequently in the relegation of the man of science to an advisory role. He sits on an advisory committee, which gives answers to such questions as may be asked it. But the authorities are under no obligation to ask questions, and the result may be the partial or total sterilization of science in that field. In any event, as every research worker knows, half the battle in science consists in asking new questions which the non-scientist cannot be expected to think of.

The authors conclude that somehow means must be found for short-circuiting the present devious and dampening routes between science and the problems to be solved—or, in other words, between men of science and the men with difficulties to surmount. The authors have some hard things to say about the refusal of many men of science to look beyond their specialisms and face their social responsibilities. This conclusion can be generalized for other walks of life: "What must be realized is that the time has definitely passed when individual responsibility could be regarded as ending with the proper carrying out of traditional functions or administrative orders. Merely doing one's duty in a conscientious and blind way is not what the situation demands. Thought, ordered and organized thought, directed to speedy decisions, is the first requirement".

The publisher in his foreword informs us that "Science in War" was conceived, written, printed, and published in less than a month. This abbreviated gestation, more characteristic of a rodent than of a human being or a book, though very remarkable, has had certain unavoidable defects. The book betrays its composite authorship rather too obviously, and there are a number of misprints (of which "The Ministry of Poland", referred to on p. 13, is presumably one !). Nevertheless it is a valuable contribution, which should be widely read and, let us hope, acted upon. J. S. H.

MICRO-DIFFUSION IN CHEMICAL ANALYSIS

Micro-Diffusion Analysis and Volumetric Error
By Prof. Edward J. Conway. Pp. xiii+306. (London: Crosby Lockwood and Son, Ltd., 1939.) 25*s*. net.

THE development of new methods of chemical analysis brings often in its train the discovery of new facts and the opening up of new fields of investigation. This is particularly true of biochemistry, where the accurate estimation of small quantities of substances in biological material may be of fundamental importance. There can be little question that the rapid progress in biochemical achievement owes much to the invention of microchemical methods of analysis applicable to biological material.

Prof. Conway's admirable book describes the application of a relatively new technique, that of microdiffusion, in chemical analysis. The Conway unit, in which the microdiffusion principle of analysis is embodied, is now well known to biochemical workers, particularly for the estimation of ammonia. With this simple apparatus distillation and aeration are eliminated and the passage of ammonia takes place by diffusion from one chamber in which it is generated into another chamber in which it is absorbed. Details of the conditions controlling this diffusion so that an accurate estimate of the diffusible substance can be made, together with details of the apparatus employed, are fully described and explained in a most interesting section of Prof. Conway's book. The microdiffusion procedure has been found already to be of value in the estimation of the following substances: ammonia, total nitrogen, urea, adenylic acid and adenylpyrophosphate, adenosine, aliphatic amines, chloride, bromide, carbon dioxide, acetone and alcohol. Prof. Conway fully describes the application of his unit to the estimation of these substances in tissues and biological fluids. This impressive list of substances will doubtless be enlarged in the future as the principle of microdiffusion in analysis becomes more widely recognized and employed.

Micro-titrations involve the use of accurate volumetric apparatus, and a knowledge of the errors to be found in volumetric analysis is obviously essential for an appreciation of the limits of the accuracy obtained in such estimations. One third of Prof. Conway's book is devoted to a very complete and valuable treatment of the errors of volumetric titration, of the errors encountered in the use of pipettes and burettes and of the corrections which have to be applied for accuracy.

A chapter on the principles of colorimetry and spectrophotometry as used for micro-analytical work, and one on the micro-techniques of Kirk and of Linderström-Lang and Holter, are useful additions to the book.

This volume is of great value to all workers interested in microchemical technique. It is excellently produced and printed, with copious drawings, curves and references. Its only drawback is its relatively high price, which might put it out of the reach of many of the students for which it is intended. J. H. QUASTEL.

PROBABILITY AND RELATIVE FREQUENCY

Probability and Frequency

By Prof. H. C. Plummer. Pp. xi + 278. (London: Macmillan and Co., Ltd., 1940.) 15*s.* net.

THE approach to probability adopted in this book is conventional, but cautious. The two definitions, the one *a priori*, based on equally likely aspects of a system, the second *a posteriori*, based on relative frequency in repeated trials, are stated and criticized, the first being preferred, but with qualifications. In the first two long chapters sixty illustrative examples of the most varied kind, divided equally between discrete and continuous problems, are posed, solved and commented upon. The reader who has worked through these will have learned a great deal about cards, dice, the Problem of Points, the St. Petersburg Paradox, Laplace's Law of Succession, Buffon's needle and many ingenious and interesting problems in geometrical probability; he should indeed be able to attack almost any reasonable problem of the kind.

In the long chapter on the Theory of Errors the normal law is derived first by Herschel's considerations, then by other sets of postulates, the conclusion being that it is "an empirical rule which is supported by experience in general, but which in the last resort must be verified by the same test". The principle of Least Squares is derived from the assumptions of normal distribution of error, and maximum probability; the other derivation, by minimum variance of consistent linear estimate, is mentioned, but as of secondary importance. (The present reviewer cannot agree with this assignment, nor with the statement at the end of § 168, p. 162, that "the basis of probability" is abandoned in this second approach; and incidentally it is not necessary for its validity that the law of error should be symmetrical.) The treatment and notation follow classical tradition.

The statistical distributions in one variable treated in Chapter iv are those of Poisson, the Type A Series with the cubic correction term, and Pearson's system, introduced by way of the limiting case of the difference equation of the hypergeometric distribution. The point of view of curve-fitting is empirical. "The results have only to be justified by success."

The criterion of "success", Pearson's χ^2, nominally appears in Chapter v, devoted to correlation, including the normal correlation function in two and three variables, correlation ratio and contingency, but also containing derivations of the distributions of χ^2, of the estimate of variance, of Student's ratio and of the ratio of two mean squares, and finally of R. A. Fisher's distribution of r, with the hyperbolic tangent transformation to approximate normality. The inclusion of these distributions adds very considerably to the value of the book. Tables of $\log_{10}\Gamma(x)$ and of the normal probability integral (in the form in which the modulus of precision is the parameter) are appended.

The book is a welcome addition to the rather exiguous list of text-books in English on the subject. Lack of space is doubtless the cause of the omission of certain important topics, such as the theory of estimation of parameters in a probability function. In a few places more precise statements could have been made. For example (p. 250), in the matter of the χ^2 test with reduced degrees of freedom, it should be stressed that the relations used in fitting the curve should be *linear* in the class-frequency deviations. Again (p. 226), for r to be zero it is not necessary that one or other of the distributions of x and y should be symmetrical; their independence is sufficient. And lastly the reviewer, holding as he does that to keep an open mind is to assign no probability whatever, must demur to the suggestion (p. 3) that "ignorance may be an element conducing to equal likeliness". These, however, are mere *obiter dicta*; the book is at all times interesting, and punctuated with dry common sense. A. C. AITKEN.

PHYSICAL EDUCATION IN GREAT BRITAIN

By Sir George Newman, G.B.E., K.C.B.

THE debate in the House of Lords on July 12 on the subject of national physical training —introduced by Lord Samuel, discussed in an admirable expository speech by Lord Dawson of Penn, and answered on behalf of the Government by Lord Clifden—has again directed public attention to the urgency of a problem which was first officially raised by the Physical Deterioration Committee of 1904, so long as thirty-six years ago. It will be remembered that that Committee held a grand inquest on the physical condition of the English people, the greatest inquiry of its kind since the Royal Sanitary Commission of 1868: "The people perish for lack of knowledge." It thus set going the action of the State to remedy matters, and recommended the medical inspection and feeding of school children, with the hygiene and physical training of boys, girls and adolescents. Indeed it made fifty-three separate recommendations, some fifty of which have now been adopted or discharged. Their beneficial effects were recognized during the War of 1914–18 by the Ministry of National Service and its Galloway Report on the physical examination of recruits in 1917–18. Now the War recalls us once more to tackle the same old problem.

From the beginning we must be clear about this problem. It finds its source in the advance of medical science, and its solution in social organization and its wise administration. First, as to its science. When Harvey demonstrated the circulation of the blood in 1616, he opened the door to an intelligible understanding of the physiological mechanism of man's body and the purpose of the blood. We now know that "the blood is the life" because it carries food, oxygen and hormones to all parts of the body, and we know also that its circulation is regulated and controlled by the operations, central and peripheral, of the nervous and muscular systems. "Through the motion of the blood," said Harvey in his famous ninth chapter, "the various parts of the body are nourished, cherished, and quickened by the warmer, more perfect, alimentive blood, which discharging its functions quickens the whole body and is indeed the foundation of life and the source of all action." Thus the first purpose of bodily exercise, whether formal or informal, whether of voluntary or involuntary muscle, is the attainment and maintenance of the growth and strength of the body structure as a whole and of its several parts. Secondly, by physical exercise we increase and develop the physiological functioning and nervous regulation of the various organs of the body, to produce a single harmony and a constant balance.

We know by experience that the living body requires food, fresh air (oxygen), warmth, muscular exercise of all its parts, and periodic rest. This has been proved to be the way, and the only way, to health and wholeness; even to survival. The heart is a muscle, the blood vessels have muscular walls, breathing is controlled by muscles, and likewise the digestive system, and thus the body becomes the power-house as well as the muscular engine of living; if we are to live, all these functions must be kept in health and vigour, in tone, readiness and quality by full and continuous stimulation. Finally, exercise keeps the body and mind one single total unity. Though its primary purpose is physical, the culture of the material body and its harmony and control, it is a means of discipline of the mind and spirit of man, to make the body its obedient instrument. Banish the exercise of heart and body and you banish life.

The practice of a regimen of voluntary exercise led the Greeks to devise systems of exercise, followed long afterwards in our own day by Swedish, German, Czech and British methods and physical philosophies. It is a feature common to them all that their social objective was scarcely less than their physical. Their greater end was health and human development, something religious, political, defensive, national, educational. This is strange but true, both in a historical and philosophical sense. Their purpose, expanding beyond the physical realm, thus became infinitely larger than merely the making of athletes or gymnasts. It was to induce manliness, to make and discipline men, to obtain a ready and perfect obedience, as Plato taught, "mainly for the sake of the soul".

Such being the basic science of physical education, there grew up, as civilization advanced, an ever-widening social purpose in its application. It is instructive to note that such purpose became the primary objective of the official recommendations of the Committee of 1904 and of the Ministry of National Service in 1919. Both of them saw poor physique, prevalent disease and high mortality, and they advocated hygiene and physical exercise as preventives; they saw unnecessary industrial fatigue in the factories delaying and reducing output, and crying for relief; they saw an urgent necessity for healthier and stronger recruits; they saw a 'half-baked' academic system of education of mind separate from body—and they both found, unanimously, that in disciplined physical education conjoined with the practice of hygiene there was a sovereign remedy, a true method both of healing and of health. Both knew that this was the task and duty of statecraft, and to its application we must now turn.

Nothing in the nature of organized physical education existed prior to 1861, when the army authorities began the physical training of recruits. It was a wooden and rather perfunctory plan of 'setting-up' exercises with dumb-bells and rifles, later amended by an infiltration of Swedish exercise. In 1871, the Education Code (following the Education Act, 1870) introduced school drill, as a meagre and half-hearted recognition of the need for physical training, following the so-called 'model' of the Army. In 1907, when the Board of Education embarked upon the medical supervision of school children, the whole subject was fully and officially explored, and in 1909 a scientific and comprehensive syllabus of instruction was issued by the Board, and physical education became for the first time an essential and integral part of the elementary school curriculum. This has developed into a complete system, with physical training organizers and trained teachers, comprising every kind of exercise, games, dancing, swimming, etc., for the elementary, secondary, technical, continuation schools and evening classes. The effect became almost magical and swept joyously through England, and, in association with medical inspection, hygiene, open-air schools, and school meals has revolutionized the health and physique of the children and young people. A comparison of the physical condition of the school children to-day with that of thirty years ago is patent, arresting and obvious to everybody.

This then is the enduring foundation of national physical education. *But it does not yet continue after school days.* The extremely precious age-period of adolescence has, with two exceptions, been neglected. For the army, navy, and air forces an excellent professional physical training has been available, and for the growing boy and girl Baden-Powell's scout movement came to the rescue, a voluntary movement which has inspired and revitalized the education of youth. Those two exceptions have saved the situation, for they have exerted an indirect effect upon the health education of the nation beyond compute. Concurrently, there has been for a long time past an enormous expansion of voluntary associations for games and sports of all kinds. Thus we have in England (*a*) the physical education of all school children, (*b*) professional physical training for the national services, and (*c*) a vast congeries of voluntary and varied agencies of leisure-time physical training following the free will and predilection of the individual. That is the three-fold scope of the English position. *It is good, but not good enough.*

Compare it with the modern German system under the Third Reich and its limitations are apparent: it is not universal, not a compulsory imposition, not for all classes and conditions, not one vast national practice which changes and unifies the character, purpose and aim of a whole people. Yet though the German system has produced a remarkable generation of vigorous and purposive youth, the English people have no desire to imitate it. For its dangers exceed its merits owing to one grave and universal defect: it ignores the individual education, growth, capacity and development of the personality, it is mechanical and 'dragooning', it is subversive of individual freedom and suppressive of national liberty, it is misdirective in purpose and ideal, for it seems to be designed solely to invent and retain a machine-made man for military service, and thus it becomes soul-destroying.

What then should we do? There are three things to do forthwith. First, we must be vigilant to maintain and make absolutely efficient our school system of a broadly conceived and wisely administered system of physical education in every school area of Great Britain, even in these difficult days of evacuation and disturbance of school education. Every child in the country, rich and poor, should receive thorough training in the practice of health and physical exercise, at the hands of competent teachers. Secondly, this inestimable advantage should be carried on through adolescence, by means of some form of continuation school or otherwise. Thirdly, the voluntary movements in physical education should be warmly encouraged, organized and co-ordinated by one central body. Fortunately, such an organization already exists, and has abundantly justified itself—the Central Council of Recreative Physical Education (58 Victoria Street, London, S.W.1). This Council is fully representative of all forms of physical training, games and sport. It has done quite invaluable pioneer work in education and demonstration in all parts of the country. It should receive sufficient financial support from the State and the local authorities to make it a still more effective instrument. What the nation needs in this problem is not more inquiries, new bodies or departments, but more united effort, power and imagination to devise ways of co-operating and utilizing the existing means and agencies.

REINFORCED WHITE FLOUR

By Dr. T. Moran and Prof. J. C. Drummond

IN the House of Commons on July 18, the Parliamentary Secretary to the Ministry of Food announced that very shortly the white loaf would be fortified with a supplement of vitamin B_1 (aneurin) and a calcium salt. It is understood that the vitamin B_1 will add approximately 100 I.U. to the daily intake, whilst the addition of calcium will ensure that all classes of the population are receiving at least the daily requirement of approximately 0·60 gm. Both constituents will be introduced into the flour stream at the mill, where accurate control can easily be achieved. This decision will probably not satisfy the advocates of brown or wholemeal bread; but it is a compromise which is sound on nutritional grounds and inevitable from the practical point of view.

The present-day straight-run white flour (73 per cent extraction) has a B_1 content of 0·30 I.U. per gram against 0·75 and 1·3 for 85 per cent extraction and genuine (100 per cent) wholemeal, respectively. These are only average figures, since the amount in different wheats varies from about 0·6 I.U. to 3·3 I.U. per gram. Taking the average consumption at 60 oz. a week, white flour at present contributes approximately 80 I.U. a day; the new flour will increase the figure to 180 I.U.

Dietary surveys have established that the nation as a whole is not receiving sufficient B_1. The League of Nations Technical Commission on Nutrition gave the figure of 300 I.U. a day as the daily need of an adult male. There is now, however, considerable evidence to show that this figure is low and, excluding the particular case of pregnant women, the minimal requirement per weighted head of the population is 400–500 I.U. per day. An analysis of Sir John Orr's 1936 survey shows that the intake of 50 per cent of the population falls below this figure, whilst a more recent survey gives the average per head figure as approximately 300 I.U. per day. The proposed supplement to white flour should, therefore, greatly reduce B_1 deficiency. Furthermore, such a step is particularly important at the present time when the deficiency is likely to be aggravated because of the possible reduction in the consumption of meat and dairy produce.

The decision to increase the calcium content of bread is of particular interest because flour—either white or wholemeal—is not an important source of this mineral: on the basis of a requirement of 0·60 gm. per day, flour only contributes about 10 per cent of this amount. There is good evidence of calcium deficiency in many diets, and obviously flour is a convenient vehicle to make it good. The ratio of calcium to phosphorus in white or wholemeal flour is 1 : 6½–10 and is, therefore, not well suited to the needs of the animal body—which are best met by foods with a ratio of 1–2 : 1. This is an argument against the addition of calcium phosphates, although they would, in fact, tend to correct the balance. One possibility is calcium carbonate which, introduced at the rate of ½ lb. per sack (280 lb.) of flour, would raise the calcium intake of Orr's lowest income groups to roughly the minimal level. Incidentally, this quantity of calcium carbonate would have no adverse effect on the palatability or general quality of bread.

The introduction of the new white flour will undoubtedly stultify the controversy about white versus brown bread, since it is mainly in respect of B_1 that the white loaf has been open to attack. There is not the same evidence that we are deficient in vitamin E or the members of the B_2 complex, which are present in wholemeal flower, while, as regards the mineral constituents, the relative merits of the two flours are uncertain because of the higher phytic acid content of wholemeal flour. The practical objections to wholemeal bread, however, are, at the moment, overriding. The evidence is that the bulk of the people prefer white bread; it is certainly true that only 5–10 per cent of the bread sold is brown or wholemeal. Again, any increase in the extraction would reduce the amount of wheat offals available for feeding stuffs and, in particular, jeopardize our milk supplies. Finally, white flour keeps very much better than brown or wholemeal flour and need not be turned over so frequently. This is particularly important at the present time on account of the vast stocks of flour that are being stored as a war reserve. Nevertheless, Mr. Boothby made it clear that wholemeal bread will still be available to those who prefer it and at the same price as that for white bread.

The increased intake of B_1 should materially improve our general health. Beriberi is rare in Great Britain, but the effects of partial deficiency, including loss of appetite, physical vigour and disorders of the alimentary tract, the nervous system and cardiovascular system, must be widespread. It is always difficult to relate suboptimal health to the lack of a particular nutritional factor, but the recent direct experiments of Jolliffe in the United States are particularly striking. He gave a daily ration to five healthy subjects, containing only half the minimal dose of B_1, and found that, within five days, four of the subjects showed characteristic signs of B_1 deficiency, including fatigue and lassitude, anorexia, precordial pain, burning of the feet, muscle cramps and palpitation. The introduction of an increased amount of aneurin into the diet caused all these symptoms to disappear within three days.

So much for the nutritional aspect. As regards the appearance and palatability of the new bread, careful tests have shown that aneurin is absolutely inert and has no effect on the dough, the volume of the loaf or the crumb character of the bread. Furthermore, due to the acid *p*H of flour, approximately 5·4, the aneurin is quite stable and there is no loss during doughing or baking. The flour will, therefore, be indistinguishable in appearance and handling properties from the present-day flour.

The introduction of the small amount of aneurin necessary will present no difficulty. It will be first mixed with a suitable quantity of flour, and this concentrate will be added at the rate of 1 oz. per sack. Equipment is in existence for doing this, and tests have already been made showing that there will be no difficulty in obtaining uniform distribution of the aneurin throughout each sack and in the entire flour stream. Determination of the aneurin in the flour and bread is possible by the thiochrome test with an accuracy of at least 4 per cent.

The new loaf, which has been under consideration for some time past by the milling industry and the Ministry of Food, now has the support of the Scientific Food Committee under the chairmanship of Sir William Bragg. Viewed from the general aspect of the nation's food, it is a revolutionary advance, because it can only mean that, in the future, whilst the preferences of the public will always receive first consideration, steps will be taken to make good any nutritional deficiencies both in individual foodstuffs and in our diet as a whole. The new loaf, in fact, with its supplement of vitamin B_1 on one hand and calcium on the other, embodies this general policy. There will now be two outstanding examples of fortified foodstuffs, bread and margarine—incidentally, both of first importance in the food of the poor.

PLANT DISEASE IN RELATION TO THE PUBLIC*

BY PROF. W. BROWN, F.R.S.,

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

THE term 'plant disease' is used in somewhat different senses. As typical examples one would cite such troubles as rust, mildew, damping-off of seedlings, etc., in which the higher plant is attacked by a parasitic fungus or similar plant organism. The destruction of fruit blossom by a late frost or the failure of a crop from drought or malnutrition are not commonly looked upon as the effects of disease; but it is logical to extend the term to include such cases. This has been the practice in human pathology where, for example, a group of 'deficiency diseases' is well recognized. Similar troubles occur also in plants. One speaks, therefore, of the physiological as against the parasitic type of disease, a division which is convenient, though in practice it is not possible to draw a hard and fast line between them.

Again, it is customary to distinguish between diseases and pests; for example, rose mildew is a disease, rose aphis is a pest. It is usual to apply the term 'pest' when the parasite is an animal, but again there are exceptions. Thus one speaks of the eelworm disease of narcissus, though the causal agent is an animal. The line of demarcation is distinct in theory, but pests and diseases are often interlinked, as in many virus diseases of plants.

For the present purpose, the effect on the crop is the matter of chief interest, and this may be the same whatever the causal agent—whether it be fungus, bacterium, virus, insect, nematode, etc., or whether the cause be strictly physiological. The effect may be sudden, leading to death of the plant at a very early stage, even before germination; or the plant may flourish for a long time and then be crippled or destroyed as it reaches maturity; or finally the product of the plant may be attacked in storage. Again, according to the nature of the causal agent, the damage may be unavoidable, or it may be partially or completely eliminated by proper precautions or treatments. Such details are for the consideration of the technical expert; the public are concerned with the final result, namely, that for one reason or another there is a material reduction of the quantity or lowering of the quality of the particular product.

---

* From a Chadwick Public Lecture delivered on June 20.

Plant diseases occur in varying intensity from year to year and place to place and cause a general wastage of plant material. It is, however, when they occur in epidemic form that they excite the public interest. Such was the great Irish potato famine of 1845–47. In 1845 Ireland carried a population of more than 8¼ million, consisting mainly of peasants whose staple crop was the potato. There had been partial or local failures of this crop previous to 1845, but in this year appeared a new disease which blighted foliage and tubers. In the following year it came earlier and in severer form. Contemporary accounts speak of the suddenness of the outbreak and of the devastating effects over large areas. By 1847 the severity of the disease had somewhat abated, but distress and disorganization were now widespread. There was absolute starvation in certain districts and nearly half the population were in receipt of relief. An outstanding result of the epidemic was a wholesale emigration to Britain and America, so that the population of Ireland had fallen in 1853 to a little more than 6 million.

Other noteworthy examples are the coffee rust epidemic in Ceylon which ruined the coffee industry in that country and forced the planters to turn their attention to tea cultivation, and the many rust epidemics of wheat which have occurred on the continent of Europe and in North America.

The risk of a world-wide scarcity of important plant products, which may arise from disease in epidemic form, has been much reduced by the opening up of large new areas of production in the various continents, and by great improvements in methods of storage and transport. Within the past twenty years the problem has at times been rather the converse one, namely, the incubus of too much of certain important plant products. Thus one read of coffee beans being used as fuel in Brazil, of fields of cotton being ploughed under in the United States, and of British farmers being penalized if they planted more than a certain acreage of potatoes. It is curious to reflect that a widespread drought in North America, which led to an extremely low yield of cereal crops, was hailed by the commercial world as a blessing, as it tended to "right the statistical position". In such conditions the biological worker, who aims at devising methods for increasing the productivity of the earth, may wonder what his function may be. Perhaps he can fortify his mind by doubting the reality of those surpluses which weigh upon commerce, and by asking, for example, whether a surplus of wheat means that no person is underfed.

Attempts are often made to assess the losses in money value which follow from particular plant diseases, but it is doubtful if much significance can be attached to calculations of that sort; the relevant data are difficult to obtain and may be difficult to interpret. The conditions which govern the trade in the commodity have an important modifying effect, as the following examples will show.

A reduced yield of wheat in Great Britain, by whatever cause it is produced, has a very small effect on the world price of wheat. The supply of wheat to the British market is not materially reduced, since wheat is easily transported and in fact Britain depends to a large extent upon imported wheat. The consumer, therefore, is scarcely affected, whereas the British producer loses more or less in direct proportion to the shortage of his crop. Now contrast this with the effect of a shortage or a surplus of the potato crop. Britain is practically self-contained with respect to potatoes. If the crop is abundant, prices fall. There is little tendency to increased demand, as potatoes are among the cheapest of foodstuffs and fluctuations in the retail price have little effect upon the quantity consumed. When, however, as a result of drought or blight or wastage in store, the crop is insufficient to meet the year's requirements, the price rises in a remarkable manner. Thus in consecutive years it may vary from about £2 to £10 per ton, that is, from a price which gives no profit to the farmer to one which is very profitable. It is notorious that, under the conditions which prevail in Britain, the potato crop yields a profit to the grower only in years when disease (in the wide sense) is most prominent.

A curious illustration of the effect of disease on prices was seen on comparing the market prices of a number of vegetables at the beginning of March 1940 with the corresponding prices a year earlier. Apart from effects arising from the War, a substantial difference was that the severe frost in January and February of 1940 had destroyed practically all the green winter vegetables. Nevertheless, the rise in price of the latter was no more than about 50 per cent, whereas such vegetables as parsnips and carrots, which suffered to a much less extent, were quadrupled in price. Obviously there was a general change-over in demand from one type of vegetable to another, and the effect of the frost cannot, therefore, be assessed on the basis of the change in price of the products primarily affected.

In the three examples just given the effect upon price of reduced quantity, as caused by disease, has been considered. Another aspect of the question is illustrated by the relation of scab disease to the market value of apples. In its severest form this disease renders apples totally unmarketable, but more usually the effect is that the fruit bears superficial blemishes which detract somewhat from its appearance without in any way impairing its eating quality. Nevertheless, the presence of traces of scab brings about a remarkable lowering of the market value. This is partly because of popular fancy, but the main reason is that fruit, even if only lightly scabbed, cannot well be kept in storage—on account of water-loss through the scabbed areas—and must, therefore, be thrown upon the market during the period of glut. Scab-free fruit, on the other hand, can be held in storage for several months, and marketed in an orderly manner in a period of relative scarcity. The effect of disease in this case is primarily upon the quality of the product, which controls the quantity available at certain times of the year.

The aim of the research worker in plant diseases being to reduce the ravages so caused, it may now be asked—who is it that benefits by any advances which are made? From the national point of view, in times of peace but more especially in times of war, there can be no question as to the benefit. If a 50 per cent yield is by some technical advance converted into a 90 per cent one, then 50 acres are made to do the work which formerly required 90, and to that extent the effective productive area of the country is extended. From the consumer's point of view the benefit is also obvious, as increased supply leads in general to freer and wider consumption and to a rise in the standard of living. It is when we come to the producer that we meet with a mixed reaction. Producers are competitors, and it is undoubted that an advance in methods of dealing with plant disease may bring immediate loss to some of them. The more skilled or the more fortunately situated may lose some of their former advantages. Two examples will make the point clear.

The disease known as 'reversion' was for many years a limiting factor in the production of black currants. Effective methods of combating reversion are now known and put into practice, with the result that the cost of producing the crop has been reduced by nearly one-half. It is stated that whereas in the past certain growers—presumably those with special knowledge—made handsome profits, nowadays there are too many growers who possess the necessary information, so that profits have become much more ordinary. The benefit, as is usual, has come to the consumer in a cheapening of the fruit.

The second example relates to the potato industry. On account of the prevalence of certain virus diseases in the warmer parts of Great Britain, stocks of potatoes lose their productive capacity and require to be replaced by more vigorous planting material from the colder and wetter parts of the country: hence the seed-potato industry of Scotland and Ireland. It is obvious that if an effective economic method were devised whereby the cropping power of English seed potatoes could be maintained, the inevitable result would be the elimination of an established industry in Scotland and Ireland.

Examples of this sort could be multiplied. Plant disease is largely conditioned by differences in climate, soil, cultural methods, etc., and thus varies in importance from one district to another. While it is to the interest of the individual producer that the diseases from which his own crops suffer should be suppressed, it does not follow that the group of producers is equally interested. It is important to recognize this fact, especially in its relation to the initiation of research on plant disease. It may seem a plausible suggestion that the farming class should subsidize research, for the reason that it is their crops which are damaged by disease. This argument is in many cases fallacious, and it would be more correct to say that the initiative should rest with the central authority in its capacity of guardian of the general public.

Plant disease plays an important part in determining the location of various crops and the manner of their cultivation. Climate and soil may be the predominant factors, but these often operate through associated plant diseases. A striking example of this relationship is seen in the location of the seed-producing areas. These tend to develop in parts which have a low autumn rainfall. Seed-bearing plants are extremely liable to damage by fungi in wet weather, especially after the flower has faded, with the result that the yield is lessened, the seed is of poor germinative capacity and is liable to carry infection to the new crop. The location of the 'seed'-potato industry, already referred to, affords a second illustration, though here the favouring conditions are precisely the opposite, seed potatoes of high cropping quality being produced in the wetter, colder areas. The explanation of this apparent anomaly is simple. Loss of cropping power in potatoes is caused by a number of virus diseases which are transmitted by aphides. The latter are much less abundant where the climate is cold and wet, and therefore the tendency to dissemination of virus diseases is much reduced.

A further impact of plant disease upon agricultural trade is seen in the various restrictions which legislatures have imposed in the attempt to prevent or limit the spread of infective plant diseases. These operate between one country and another or even between different parts of the same country, and take the form of quarantine regulations, embargoes, systems of inspection and certification, etc. It is a controversial point how far such legislative interference achieves its primary object and how far it is liable to be abused for purely commercial purposes.

Advances in the practice of combating (in technical language 'controlling') plant diseases are necessarily slow. Even when the investigator has the good fortune to devise a promising method, it must be fully tested over a range of seasons, and in relation to the variety of cultural systems which prevail in practice. Years may be spent in perfecting details, and there may in fact be no finality in this respect. When the method has been elaborated and shown to be effective and economical, it will still fail to be accepted unless the operations involved are such that they can reasonably well be fitted into the routine of cultivation. Too often the 'control measures' freely suggested in plant pathological text-books fail in this respect—they are utterly impracticable. On the other hand the urgency of controlling certain plant diseases may be so great that the go-ahead grower is prepared to modify drastically his system of cultivation in such a way as to facilitate the application of methods of disease control. This may be a very lengthy process indeed, and may require a long continued co-operation of practical grower, plant breeder, plant pathologist, entomologist and other experts. The recent history of the apple-growing industry in England illustrates this type of development, and as the public has gained very notable benefits thereby, a sketch of the 'evolution' of production may suitably conclude this article.

The old-fashioned apple orchard was planted with 'standard' trees, widely spaced, intercropped at first with bush fruit, and as a rule finally laid down to grass. The trees were expected to grow to a large size and to come into production in 10–15 years. The large size of the fully grown trees made spraying difficult and pruning very laborious. Pests and diseases tended to become rampant; much of the fruit was tunnelled by insect larvæ and, if not prematurely shed, finally invaded by rotting fungi; scabbed apples were the rule; the growth of the tree became quite unregulated; and at the best the harvest was a mass of ill-assorted fruit, unattractive in appearance, which was in the main thrown upon the market immediately after being picked. Much of it never reached the market at all, and as far as the public was concerned, English apples were abundant for about two months in the autumn, after which they were seen no more.

Consider now the more modern method. The type of tree favoured is the dwarf. This is obtained by grafting on certain types of rootstock, and so thoroughly has the interaction of stock and scion been studied that it is now possible for the grower to select the combination which will in due course produce the tree of desired size on his particular soil. The dwarf tree being closely planted and coming into early bearing, the complications which follow in practice from undercropping with bush fruit are avoided; the trees are easily shaped and pruned; growth is regulated so as to admit a maximum of sunlight to the centre, thereby enhancing the colour of the fruit and affording a partial control of fungoid diseases; the trees are manured according to well-defined principles, with considerable effect on cropping power and fruit quality; spraying against insects and fungi is systematically carried out, the smallness of the trees making such treatment highly practicable; the crop if too heavy is suitably thinned and spaced; the trees being small and sturdy, damage to the fruit from autumn winds is reduced to a minimum. The final crop may not equal in quantity what was from time to time obtainable by the old methods, but the quality is much higher.

The improvement in method goes much farther. Fruit of the quality described is capable of being stored. Much physiological research has been devoted to solving the problems of storage diseases, and new methods have been devised. The final result, therefore, is that the produce of the modern orchard is marketed steadily over a period of many months. The progressive grower has benefited financially by the change, but the greatest benefit has come to the consuming public, which can now satisfy its appetite for English apples over eight months of the year instead of two months as formerly. Stated in another way, the essential difference is that a very high proportion of the apples from the modern orchard reaches the consumer, whereas much of the crop grown by the old method was merely wasted. For this meritorious advance the plant pathologist shares the credit with other technical workers, and it is along such co-operative lines that further progress is to be sought. Lest it should be assumed that the above rosy picture applies to all crops, it may be added that there is room for further advances. There are still many crops in which the proportion of waste is extraordinarily high, and it remains for the research worker of the future to point the way to a desirable improvement.

OBITUARIES

Sir Arthur Harden, F.R.S.

BIOCHEMISTS the world over will have heard with sincere regret of the death of Arthur Harden on June 17 in his seventy-fifth year. By his late colleagues at the Lister Institute and by a host of old pupils from many lands who learnt at his feet or at one time collaborated with him, his loss will be particularly felt, for Harden who, on his retirement in 1930, had completed thirty-three years of service as head of the Biochemical Department, was in himself an institution and a veritable tower of strength in the Lister community.

A pupil of Roscoe and a lecturer in chemistry at Owens College for nine years, Harden came in 1897 to London to take charge of the Chemical and Water Laboratory of the Lister Institute, then the British Institute of Preventive Medicine with its laboratories in Great Russell Street, in succession to Mr. Joseph Lunt, who had received the appointment of assistant in physics to the Astronomer-Royal at the Cape. The Institute was then young, financially very insecure, and struggling to justify its existence to a somewhat impatient generation unused as yet to the trained professional prepared to play his appropriate part in concerted attacks on basic problems of preventive medicine. Soon, however, the position was to change for the better, for in May 1898 the Institute was able to remove to the new buildings in Chelsea Gardens and in December of the same year, the Council of the Institute was happy to accept the munificent donation by the late Lord Iveagh to the Institute's funds.

Harden's training and research experience in chemistry at Manchester and at Erlangen had been, up to the time of his joining the Institute, on strictly orthodox and classical lines, and it was on this sound foundation that he was soon to build the high reputation he later enjoyed as a pioneer of biochemistry in Great Britain.

On his arrival in October 1897, Harden found the then director, Dr. Allan Macfadyen, actively engaged in the study of the fermentative activities of the *coli* group of organisms, and at Macfadyen's suggestion he embarked on an investigation of the breakdown products of glucose. One of Harden's earliest publications on this subject appeared in 1899 in a volume not now readily accessible (*Trans. Jenner Institute Prev. Med.*, Second Series, Macmillan and Co.) but it was a subject to which he often reverted in later years. His great knowledge and practical experience of bacterial enzymes and bacterial metabolism generally enabled him to survey this whole field in masterly fashion for the "System of Bacteriology" (1930).

Certain circumstances of the time, however, drew Harden inevitably to the problem of the chemistry of the yeast cell, which formed the chief preoccupation of his working life for some thirty years. In 1897 Buchner had demonstrated the fermentation of sugar by the pressed yeast juice, while the interest taken by certain members of the Council of the Lister Institute in industrial fermentation processes had led in 1899 to the establishment of a Hansen laboratory under the direction of Dr. G. Harris Morris. This laboratory was, a year later, merged in the general chemical laboratory directed by Harden. Further, the efforts of Macfadyen and Rowland to secure the juices of pathogenic bacteria by grinding at the temperature of liquid air, an elaborate plant being available for this purpose, represented at least cognate inquiries to those on which Harden and his first collaborators, Sydney Rowland and W. J. Young, embarked with yeast juice as the object of test.

Here is not the place to follow in detail the story of the discoveries made by Harden and his collaborators in the course of their many years study of the chemical processes involved in the fermentation of sugar by yeast juice. That study is truly classic, and its issues have not only illuminated our knowledge of the chemical processes within the yeast cell but have also provided clues to the chemical dynamics underlying such seemingly remote processes as muscular activity and ossification of bone. For his work on alcoholic fermentation Harden was in 1929 awarded the Nobel prize in chemistry, shared with von Euler.

The yeast cell has been a gold mine to many kinds of diggers, and not least to those immersed in vitamin studies. It is not surprising, therefore, that Harden towards the end of the War of 1914–18 entered the nutritional field for a time, and with his colleague Zilva contributed a series of valuable papers on the antiscorbutic and antineuritic vitamins and their occurrence in various foods and drinks, not excluding beer.

Harden's outside links and interests were numerous, but perhaps his services as editor-in-chief of the *Biochemical Journal* for twenty-five years from 1913 until 1938 deserve special mention; for the influence he was able to exert in this capacity on the development of biochemistry in Great Britain has been incalculable.

Many honours came to him; an honorary LL.D. from Manchester and from Liverpool, an honorary D.Sc. from Athens, the Davy Medal of the Royal Society awarded him in 1935 and the honour of knighthood in 1936. Until some nine months ago, Harden continued to visit the Institute every day from his home in Bourne End and his interest in all the activities of the Institute never flagged. At his death he had been for nine years a valued member of the governing body of the Institute. A widower for twelve years, Sir Arthur leaves no family. To his sisters we would extend our sincere sympathy.

J. C. G. LEDINGHAM.

Mr. E. R. Gunther

It is barely two months since NATURE regretted the passing of Dr. R. T. Gunther; now comes the untimely death of his eldest son, Eustace Rolfe Gunther, at the age of thirty-seven, accidentally shot while on active service. This tragic event robs oceanography of one of the most virile of its younger workers. Educated at Winchester and Caius College, Cambridge, he was appointed as zoologist in 1924 to be one of the original members of the scientific staff of the Discovery Committee set up by the Colonial Office to investigate the resources of the antarctic seas, particularly in regard to the factors, biological and physical, governing the great whale fisheries of those waters.

It was my privilege to be closely associated with Gunther on the R.R.S. *Discovery* on her voyage of 1925–27, on the smaller ship R.R.S. *William Scoresby*, and afterwards in the joint authorship of an extensive report upon the ecology of the antarctic plankton. He was a man of sterling qualities. Working with him day and night, often under the difficult conditions presented by the Southern Ocean, one was continually impressed by his deep sense of duty, his devotion to his work, and his tireless energy. His enthusiasm was always combined with a scrupulous regard for accuracy: both in the field and the working-up of data. After working at the nets and water-bottles for thirty-six hours on end, except for odd moments snatched for hurried meals, it was only the fear of being inaccurate in the readings and recordings, not fatigue itself, which persuaded him to rest. He had a love of the sea and the open life; he was a real deep-water oceanographer, with the determination to bring back results.

In 1931 on the R.R.S. *William Scoresby*, Gunther led a highly successful expedition to investigate the Peru Coastal Current (sometimes called Humboldt's Current) and published in 1936 a comprehensive report on its physical, chemical and biological aspects. Later he again visited the Antarctic on a whale-marking expedition to study migrations, and made valuable observations on the swimming and breathing habits of whales (a paper now in the press). Much of his time before the War was spent in working on the material collected during a trawling survey, partly carried out under his direction, on the extensive banks lying between the Falkland Islands and South America. It is to be hoped that all the work he put into this will eventually be published.

In addition to his wide interests in zoology and oceanography, Gunther was always delighted to record any unusual natural phenomenon; his recent letter in NATURE on the ice storm in Wiltshire is an example of this. Colour and scenery were a great joy to him, and he did splendid water-colour drawings, both sea and landscape, as well as accurate colour studies of marine animals. Many will treasure his privately printed "Notes and Sketches made during two years on the Discovery Expedition".

It was characteristic of Gunther's capacity for work that his long leave after the 1925–27 expedition should have been spent in the Department of Biochemistry at Cambridge, undertaking researches on the fatty and vitamin content of plankton (published in collaboration with G. Collin, J. C. Drummond and T. P. Hilditch). His published work, while extensive, is no real measure of his industry. He was always being attracted by side branches which he felt it his duty to explore, and only when he had carried them a long way did he realize he was being taken too far from the main issue; reluctantly they were put on one side for some later available time—alas, now no more.

In 1937, distressed by Great Britain's unpreparedness for war, Gunther joined the territorials as a sapper and was commissioned a year later. On inquiry about the best use a man of his training might be, he was advised to enter the searchlight service, and his keen powers of observation were of particular use in training spotters. He was born on September 20, 1902. In 1929 he married Dr. Mavis Carr and leaves a son and two daughters. He was essentially happy in his work and family life, and was devoted to both. He has been a worthy upholder of the tradition set by his father, his grandfather, Dr. A. G. L. G. Gunther, F.R.S., and his great-uncle, Prof. W. C. McIntosh, F.R.S.

A. C. HARDY.

Dr. Wilhelm Stekel

DR. WILHELM STEKEL, the well-known psychoanalyst of Vienna, who died in London on June 27, was born at Bojan in Bukowina on March 18, 1868. He received his medical education in Vienna, where he was one of Krafft-Ebing's pupils, and qualified in 1893. After some years general practice he devoted himself entirely to neurology and psychiatry. He was one of the first medical men to be interested in psychoanalysis, and from 1896 until 1912 when, like Adler, Breuer and Jung, he assumed his independence, he was one of Freud's chief supporters. He was a very prolific writer. His principal works, which were all translated into English, are "The Beloved Ego" (1921), "Psychoanalysis and Suggestion Therapy" (1923), "Peculiarities of Behaviour" (1924), "Disorders of the Instincts and Emotions" (1929–1930), and "The Homosexual Neurosis" (1933). From 1910 until 1913 he was co-editor with Freud and Adler of the *Zeitschrift für Psychoanalyse*, and in 1924 became editor of *Fortschritte der Sexualwissenschaft und Psychoanalyse.*

WE regret to announce the following deaths:

Prof. J. G. Dusser de Barenne, Sterling professor of physiology in Yale University, on June 9, aged fifty-five.

Mr. C. Rawson, head chemist of the British Cotton and Wool Dyers' Association during 1917–20, aged eighty-one.

Prof. D. Riesman, professor of the history of medicine in the University of Pennsylvania, on June 3, aged seventy-three.

NEWS AND VIEWS

Ideals of Democracy

MR. ROOSEVELT'S broadcast, on accepting the nomination of the Democratic Convention for election to a third term of office as president of the United States of America, was inspiring in its note of lofty and patriotic self-sacrifice, no less than in its determination to maintain unswervingly in foreign policy the sympathy and moral and material support of all free peoples resisting the aggression, which has "wiped out ancient liberty-loving, peace-pursuing countries". Mr. Roosevelt contrasted the totalitarian States—"a relapse into ancient history"—with the democracy which can hold the votes of "the common people . . . only when it adequately respects their dignity by so ordering society to assure to the masses of men and women reasonable security and hope for themselves and their children". He went on to say that the democracies, both that in the United States and those still unconquered, "would never willingly descend to any form of that so-called security of efficiency which calls for the abandonment of other securities more vital to the dignity of man". Point is added to the clear-cut contrast by recent German propaganda culminating in the speech of Herr Hitler in the Reichstag on July 19. From these emerge a picture of Europe in the peace of the Chancellor's professed desire in which the non-Germanic peoples are the helots of a conquering caste—a reversion to the tribal domination of the Germanic migrations and invasions, which is the cardinal fact in Hitler's view of European racial and national history. It is well that he recognized that this conception of a European policy is so far incompatible with the ideals of democracy as to make inevitable the complete and final destruction of one or other of the two antagonistic systems.

Re-organization

WHILE it has been stated with every shade of emphasis and in constant reiteration that the democracies fight for freedom and justice, the need has been felt to counter German propaganda by a more concrete expression of the manner in which these ideals will be given effect in a post-War world. Although for the moment the immediate future is alone the matter of vital concern, yet science can afford, and indeed must, take a longer view even at this critical moment. The mistakes of the period immediately after the War of 1914–18, which sought to re-create a pre-War society that had for ever passed away, must not be repeated. The problems which will have to be solved after the present War must be approached with a complete change of heart from that of the vanished pre-War period. Narrow concepts of national self-sufficiency in political and economic relations will perforce have been dissipated. In their place the ideal for which we must strive with a burning enthusiasm more potent than the fanaticism to which Hitler attributes his present successes, is not merely our continued existence as a people. We must be prepared to sacrifice our all in the cause of the right of every individual man and woman to participate fully and freely in the duties no less than in the privileges of a world order based on mutual help and trust and not on force, a world in which the concept of the State has broadened into that of an instrument of the well-being of the individual citizen and not an overriding end in itself.

Man's Passion for Freedom

GENERAL SMUTS in his well-considered and judicial broadcast from South Africa on July 21, drew a favourable augury for the outcome of the coming attack on Great Britain from the indomitable spirit and unfailing courage of Allied troops in the withdrawal from Dunkirk. Against such a rock the waves of attack will beat in vain. It is, however, the spirit which informed the broadcast by Lord Halifax on July 22 which will bring victory—"the unconquerable passion of man for freedom". Hitler's policy he denounced as the gospel of hate, the policy of brute force, his message to mankind the enthralment of the human spirit under ruthless tyranny. It is perhaps permissible to suggest here that the fanaticism of Germany's irruption over the peoples of Western Europe admits a second comparison with 'ancient' history—the great fanatical spread of Islam. Then in east and west, in Spain and in Palestine, it fell to the peoples organized under the banner of Christianity to turn back the tide of invasion of an alien faith. The present war also is a struggle of the *spirit* of Christianity against the brutal force of paganism. As Lord Halifax said, "We must march together in this crusade for Christianity. We and our great Dominions oversea stand, and shall continue to stand, four-square against the forces of evil".

Advisory Research Council of the Chemical Society

THE Advisory Research Council of the Chemical Society (A.R.C.C.S.) still finds itself unable to suggest work of national importance to all of the large number of chemists who have volunteered their services, although more than a hundred topics have already been allocated. Hence it would be appreciated if research committees under Government auspices could make known to the Council the existence of chemical problems just below the level of priority which justifies the expenditure of public funds in the attempt to find a solution. There is in particular a dearth of worth-while problems of a physico-chemical nature.

At its last meeting the A.R.C.C.S. decided to interpret its functions in an elastic manner, and it is now prepared to organize the preparation, in laboratories of universities and technical colleges, of fine chemicals required for any purpose by Government departments, institutions or services or even for approved research purposes in other universities. It is a *sine qua non* that such substances are not available commercially and that the manufacturers of fine chemicals are unable, or do not find it convenient, to meet the need. The arrangement proposed is that the substances shall be made and supplied on a cost price basis, and it is understood that purchases made in this way will require no special Treasury sanction, being in fact acquisitions to stores. The secretary of the Advisory Research Council is Mr. S. E. Carr, Chemical Society, Burlington House, Piccadilly, London, W.1.

Registration of Chemists

COMPULSORY registration on the Central Register of the Ministry of Labour, which was applied last week to engineers, has now been extended to chemists, physicists, and quantity surveyors. The order referred to all possessing a science degree of a university of the British Empire including chemistry or physics and, in certain circumstances, those who passed the corresponding intermediate examination, or have similar standing in these subjects; also to those who have received training as quantity surveyors. These registrations will supplement the names of those already voluntarily on the Central Register.

Physical Problems in Industry

IN order to assist professional men who in the present emergency find themselves presented with technical problems in applied physics of which they do not happen to have had previous first-hand experience, it has been decided to extend the facilities of the Institute of Physics' panel of consultants. Through this medium inquirers are put into touch with those physicists most likely to be able to offer immediate practical suggestions in any particular case. In the first instance the contact is quite informal; subsequent arrangements are a matter for private agreement between those concerned. The subjects which can be dealt with cover all branches of physics, both pure and applied, including, for example, physical measurements and testing, the design and supply of scientific instruments for special purposes, and the control of processes by physical means.

By acting as a clearing house in this way and supplementing existing official and unofficial organizations, it is hoped to help in the national effort by directing attention to existing solutions of difficulties which, while appearing to be new problems, are often already well-known in other fields. A typical example will serve to illustrate this point. A recent inquiry related to possible means of measuring the flow of certain animal secretions having complex physical properties, which prevented the use of more usual methods. It happens that certain printing inks have somewhat similar properties, and an informal introduction to a physicist in that industry has proved of great assistance. Inquiries about this scheme should be addressed to the Secretary of the Institute of Physics at the University, Reading.

The B.P. Standard for Ipecacuanha

FURTHER modifications in monographs of the British Pharmacopœia have been effected by way of notice in the *Gazette* of July 5. The chief one is an alteration in the standard for the alkaloidal content of ipecacuanha. The direction in the B.P. 1932 requires the root to contain not less than 2 per cent of the total alkaloids of ipecacuanha, calculated as emetine, of which not less than two thirds consists of non-phenolic alkaloids, calculated as emetine; the change now made is the substitution of "three fifths" for "two thirds". Although the reduction in the standard is but slight, it will have a marked effect upon the availability of a drug which is regarded by the medical profession as an extremely important one, whether prescribed in the form of Galenical preparations, or as its alkaloid emetine, which is a specific in tropical dysentery. The 1932 test excluded from official recognition large importations of the root from Bahia and Minas Geraes, eastern States of Brazil, and virtually restricted the source of the standard drug to the western State of Matto Grosso. With the requirement as to the alkaloidal content reduced by a fifteenth, a substantial proportion of the shipments from the eastern States of Brazil will now conform to the B.P. standard. Thus the security of ipecacuanha root will be relieved and a reduction in the cost may be expected.

Air Raid Precautions

FOLLOWING the issue of the popular pamphlet "Your Home as an Air Raid Shelter", of which more than 700,000 copies have been sold, the Ministry of Home Security has now issued a second pamphlet called "Air Raids: What You Must Know: What You Must Do". This pamphlet is a complete 'potted' A.R.P. course for the general public. It tells the ordinary man and woman everything he can need to know for the protection of himself and his family in air raids, and to enable him to help his neighbours. It deals with such subjects as protection against bombs, behaviour during and after a raid, how to deal with incendiary bombs and war gases, and contains a simple first aid course. It tells the householder all about the warning system, how to make repairs to his house after a raid, and contains a wealth of practical information on all these subjects. The book is fully illustrated with photographs and diagrams. It can be obtained through any newsagent, price 3*d*., or price 4*d*., including postage, from the Stationery Office, York House, Kingsway, London, W.C.2. The pamphlet will be invaluable to members of factory and other A.R.P. squads.

Utilization of Aliens in National Work

SIR JOHN ANDERSON, Home Secretary, in a written answer to a question in the House of Commons on July 18, stated: "I have already given instructions to the police which I hope will prevent the internment of specialists or 'key' workers engaged in connexion with Government contracts or essential export trade. If in any individual case such a person should nevertheless be interned, it is open to his firm to make representations to the appropriate Government Department, and I am always ready to consider the question of releasing any internee who is certified to me by a Government Department as willing and able to render services of importance to the community."

Czech Culture under German Rule

DR. BENEŠ has written a restrained but authenticated account of some of the Nazi crimes in a pamphlet (London: Allen and Unwin. 6*d.*) which has just appeared. It was the pride of the Czech nation that its culture, bound by numerous traditional ties with Britain and the West, was acknowledged by the whole civilized world. Now, after more than a year of German occupation, relics alone remain. The Nazis have attacked all sections of cultural life in an attempt to destroy the fundamentals of Czech national ideals. Besides the universities and colleges, many schools are closed and modern educational buildings used as barracks, so that the education of Czech children is impossible. The dictum of the Nazi commissioners is that "for the Czechs as an *Arbeitervolk* elementary schools are sufficient". These serve for mass Germanization. School books have been "revised", and new ones with Nazi theories are systematically imposed upon the nation.

Meanwhile, twenty thousand students have been driven from their lecture rooms, and those employers who tried to alleviate their lot by giving them employment have been punished. Scientific equipment has been destroyed, valuable libraries wrecked and books and volumes of scientific journals burned or at best carried off to Germany. Results of years of research by Czech professors lie as rubbish on the floors of the lecture rooms and laboratories. The professors (some hundreds) and their assistants (about a thousand) were not allowed to take even their private possessions and note-books from their rooms; many have been sent to concentration camps and others given minor duties in administrative offices for which they were not fitted. The pamphlet merits the attention of learned men throughout the world and should arouse them to the danger now facing civilization.

Seasonal Mortality in England and the United States

SEASONAL variation of mortality has long been a fact of common knowledge, and its cause the subject of speculation. The maximum invariably falls in the first quarter of the year and the minimum in the third quarter. The difference between the two quarters is considerable; in 1931–35 the maximum was 60 per cent greater than the minimum. Is there any way, it may be asked, of reducing this difference, or is the winter excess due to causes of death over which at present we have little means of control? A comparison of the mortality figures of England and Wales with those of the United States shows that the winter peak is higher in the former, although in summer they fall to a lower point than the United States figures.

This seasonal difference of mortality in the two countries has been the subject of a detailed statistical study by Dr. Lewis-Faning (Medical Research Council, Spec. Rep. Series, No. 239. H.M. Stationery Office, 1940. 1*s.* net). He reaches the conclusion that the winter disadvantage and the summer advantage of Great Britain are not due to climatic factors only, but are both also dependent, at least in part, on factors of mortality preventable in some degree. Thus, the main contributors to the British unfavourable winter balance are influenza, respiratory tuberculosis, bronchitis and pneumonia, and it has long been held that the last-named is at least partially preventable. The two most important contributors to our summer advantage are diseases of the heart and deaths from violence. The former shows a large decline in summer in both countries, the latter reveals no decided seasonal variation in Great Britain but a large summer rise in the United States. The relatively high rate of mortality from this cause in the United States is clearly one that may be open to attack.

Cambridge University Botanic Garden

BOTANICAL gardens contribute living interest to the teaching of plant science, and it is significant that their development began in the earliest days of the study of botany. The University of Cambridge was not one of the first bodies to recognize the value of providing living plants for study, but it had some early associations with botanical science. Mr. F. G. Preston has published an interesting paper on the history of the gardens now under his charge (*J. Roy. Hort. Soc.*, 65, Pt. 6, June 1940). The famous Gerard attempted to establish a botanical garden at Cambridge in 1588, but without success. John Ray studied the Cambridgeshire flora, and later handed his mantle to the University's professor of botany, John Martyn, who extended the floral studies to other counties, and lived to see the first botanic garden at his University. In 1762, Dr. Walker, vice-master of Trinity College, obtained about five acres of land, on the advice of his friend, Philip Miller of Chelsea. The garden remained in poor condition until 1831, when Prof. Henslow was successful in obtaining the present site, and transferred the plants to their new surroundings. The names of Babbington, Lynch, Marshall Ward and Sir Albert Seward show to what extent the directors of the garden have contributed to the development of modern science, and in more recent times W. Bateson and Prof. R. C. Punnett have worked there. Development after the War of 1914–18 was along the lines of closer contact with the teaching of botany, and was associated particularly with the names of Reginald Cory and Humphrey Gilbert-Carter.

Accessions to the Fitzwilliam Museum, Cambridge

THE annual report of the Fitzwilliam Museum, Cambridge, for the year ending December 31, 1939, includes in a considerable list of accessions in the period a number of no little archæological interest and importance. Among these a bequest of an Egyptian bronze cat of the Twenty-sixth Dynasty by the late Claude G. Montefiore is said to be "the best of the type in the department". A steatite figure of Amen-ra and a hæmatite amulet of Ta-urt given by the director (Mr. L. G. C. Clarke) were the only further additions to the Egyptian antiquities apart from a valuable collection of choice specimens given by Mr. G. D. Hornblower. Mr. Hornblower was also the donor of two Chinese paintings on silk, a makimono and a sketch-book by Hokusai, another Japanese sketch-book, two Persian miniatures and a Coptic iron cross.

The Oriental Department also received some notable examples of Chinese ceramic art made specially for export, among these a porcelain bowl made for the Siamese market, given by Prof. Ellis H. Minns, of Pembroke College, and from the Hon. Lady Darwin another porcelain bowl which had been made for the European market, while an unusual punch bowl, intended for the same destination, was bequeathed by the late Lieut.-Colonel K. Dingwall. A Kutahia cup was a donation from Prof. Percy E. Newberry. In the Greek and Roman Department the most important acquisition was a fine south Italian bronze cinerary urn of the late sixth century B.C., purchased at the W. R. Hearst sale out of the Greek Antiquities Fund. Miss Winifred Lamb, honorary keeper of the Department, presented a Falisean skyphos of the fifth or fourth century B.C.

British Museum Library Extension

THE 'Iron Library' extension, which is now being completed at the British Museum, London, by H.M. Office of Works, is an interesting development in the introduction of welded steel work. The present structure is in the nature of an innovation, as it is the first example of an all-welded structural frame to be adopted by the Office of Works. The main factors influencing this decision were the greater neatness of the welded joint and the saving in headroom which it permits. It was designed to augment the bookshelf capacity of the Library. The extension occupies the north-east quadrant of the rectangular plot surrounding the historic Circular Reading Room and replaces a part of the existing structure of wrought iron and timber. In *Electric Welding* of May 1940, published quarterly by the Quasi-Arc Co., Ltd., of Bilston, Staffs., an instructive technical description, with photographs, is given of the building during the process of construction. Messrs. Dorman Long and Co., Ltd., are the constructors for the structural steel-work. They prepared and rolled the special sections; more than 500 tons of steel-work were necessary. Each welded joint was made in three runs from a No. 10 gauge electrode. The total number of welds in the structure exceeds 60,000. The welding has been carried out with a maximum of ten operators, who between them have used about 47,000 quasi-arc electrodes. The necessary welding current was drawn from quasi-arc Diesel, petrol and transformer units.

Meteorology in Southern Rhodesia

THE meteorological report for Southern Rhodesia for the year ended June 30, 1939, by R. A. Jubb, acting chief meteorologist, is dated January 1940, but follows the general lines of those of pre-War years. Seasonal forecasts of rainfall of the type made by Sir Gilbert Walker, based on past departures from normal of meteorological elements in selected action centres in other parts of the world, were continued, and were very successful in this year. The average rainfall over Southern Rhodesia during those months that correspond roughly with the winter of 1938–39 in the northern hemisphere, that is, Southern Rhodesia's summer rainfall of 1938–39, was forecast as 11·8 in. above normal; actually it proved to be 12·2 in. above normal. This was the third year in succession during which the method was strikingly successful, and it is easy to believe that, as stated in the report, the forecasts are being found to be of practical value; there appears to be no sign that the correlation coefficients on which the forecasts are based are becoming smaller, as is sometimes the case after a considerable number of years of high correlation, for the least successful forecasting period of three years ended four years earlier. In Southern Rhodesia rain is of paramount interest, and it is satisfactory to note that whereas thirteen observing stations closed down, the number of new stations was forty-one.

Map of the Karakoram

A NEW map of the Karakoram has been published by the Royal Geographical Society (7*s*. 6*d*. or R. 5). Produced under the direction of Prof. K. Mason, it incorporates all published results of exploratory work up to Mr. E. Shipton's expedition of 1937. The scale is 1 to 750,000 and the size of the sheet is about twenty by twenty-three inches. The great altitude range from about 3,000 ft. to 28,000 ft. presented a difficult problem in representing relief. The layer colour system had to be abandoned. The contours in a region of such high relief are too close and the tint of the layer merged into the colour of the contour line. Moreover a satisfactory scheme of colour could not be found. Hill slopes are shaded with brown and purple on a general ground tint of yellow and generally the shading is cast from the north-west, but the direction varies slightly to suit the slope of the ground. Blue shading is used for snow and glaciers are white. Valleys have a layer tint of greyish-green. There are altogether eight colours and the map is a most effective piece of work. Heights are given in feet and the names employed are those decided on by the Karakoram Conference of 1937 and approved by the Surveyor-General of India.

Metal Water-Jet Pump

ALTHOUGH metal filter-pumps have been in common use for some time, the majority were imported. A new model developed and produced in Great Britain is now available. Metal filter-pumps are unbreakable and easily cleaned. In addition, the jet of the new model has been re-designed so that a high pumping speed can be reached even with pressures as low as 15 lb. in the water supply. Under suitable conditions, pressures of 15 mm. or less of mercury are reached. The new pump should therefore prove of great service in general laboratory work involving distillations, filtrations or aerations and in hospital and surgical work. The pump and further details can be obtained from Messrs. W. Edwards and Co., Ltd., Southwell Road, London, S.E.5.

Physic and Literature

UNDER the title of "Books about the Doctor in Physick and Literature", Schuman's of 738 Fifth Avenue, New York, have published an annotated spring catalogue consisting of five parts devoted respectively to medicine in literature, medical biography, history of medicine, medical portraits and Beaumont lectures. The first part, which will probably appeal to the largest number of readers, contains a long list of *belles lettres* which have reference to medicine, including in alphabetical order Aristotle's masterpiece, Balzac's "Médecin de Campagne", Sir Thomas Browne's "Urn Burial", Burton's "Anatomy of Melancholy", Casanova's "Mémoires", Defoe's "Journal of the Plague Year", Pepys's "Diary", plays of Shakespeare, and Voltaire's "Candide". The relation of medicine to art is represented by Leonardo da Vinci's drawings and the works of Eugen Holländer. The works on medical biography include those of Bland-Sutton, Jerome Cardan, Harvey Cushing, Sir Henry Holland, Edward Jenner, William MacMichael and Thomas Young. Under the heading of medical history we find works by Allbutt on Greek medicine in Rome, Donald Campbell and Leclerc on Arabian medicine, W. G. Black on folk-medicine, Sir Michael Foster on the "History of Physiology during the Sixteenth to Eighteenth Centuries", August Hirsch on "Geographical and Historical Pathology", Osler on the "Evolution of Modern Medicine", J. F. Payne on "English Medicine in the Anglo-Saxon Times", and histories of medicine by Max Neuburger and Sudhoff.

Earthquake in Tibet

ON July 15 an earthquake of considerable severity accompanied by floods was reported in *The Times* to have caused havoc in the Chumbi Valley in southern Tibet. Villages from Yatung southwards suffered considerable damage, and the telegraph line from Yatung to India over a distance of six miles has been destroyed. All the bridges over the Amachu River have been demolished and, in all, two hundred people are believed to have perished. The epicentre appears to have been near lat. 27·5° N., long. 89° E., which is a little to the south of the epicentre of the strong earthquake of January 3, 1935, and to the south-west of that of January 7, 1937.

Earth Tremors in Great Britain

ON Sunday, July 14, at about 11.59 p.m. B.S.T. a slight earth tremor was felt in Birmingham, Coventry and Leicester. No damage was done. The epicentre was probably just to the north of Coventry. Earth tremors appear to be slightly more frequent in an area somewhat to the north of Leicester, that is, nearer to Nottingham, where one was experienced on May 3, 1935, though one was felt at Birmingham on October 23, 1924. On July 16 at about 5.35 p.m. B.S.T. an earth tremor lasting several seconds was felt very strongly in the Denny district of Stirlingshire and for some miles around. In the epicentral area, a man is reported to have been thrown from his chair. The shock threw crockery from shelves and moved chairs and desks in Glasgow offices; it was felt more strongly at the top of high buildings than in the street below. No serious damage has been reported. Slight earth tremors are very occasionally felt in this district, though the area most affected by earth tremors in Scotland is near Comrie in Perthshire, where the British Association has shock recorders in action. Both the recent Coventry and Denny tremors were probably caused by slipping along local fault systems.

The Night Sky in August

NEW moon occurs on August 3 at 20h. and full moon on August 17 at 23h. U.T. The moon is in conjunction with Mercury on August 2, with Saturn and Jupiter on August 24, and with Venus on August 29. Jupiter and Saturn rise after 22½h. at the beginning of the month and shortly after 21h. at the end, the two planets remaining within 1½° of each other. Although conjunction between them occurs on August 15, their closest approach (1·2°) is on August 7. Venus is the brilliant morning star, at greatest brilliancy on August 2, when it rises shortly before 1h. 45m. U.T. At the time of conjunction with the moon on August 29, it may be looked for in daylight north of the moon. A telescopic view of the planet will show it to be crescent-shaped throughout the month. Mercury, an elusive object at most times, should be easily seen in the east before sunrise, especially on August 10 when it reaches its greatest elongation (19° west). On August 10–12, the Perseid meteors reach their maximum frequency. Their radiant point moves from Andromeda to Camelopardus. The Milky Way and its associated constellations, rich in interesting objects for telescopic or binocular study, is well placed near the meridian after dark, especially towards the end of August, when the moon does not rise until the early morning.

Announcements

DR. WILLIAM W. WATSON has been appointed professor of physics in Yale University, in succession to Prof. John Zeleny, who retires this year.

THE degree of D.Sc. has been awarded by the Queen's University, Belfast, to R. C. Pink (chemistry) and C. T. Ingold (botany).

THE National Council for Mental Hygiene, 76 and 77 Chandos House, Palmer Street, London, S.W.1, has arranged for a conference to be held on July 30 at the British Medical Association House, Tavistock Square, W.C.1, to discuss psychological problems arising out of war conditions as they affect the teacher.

THE first volume in Braille dealing with botany has been prepared from a series of broadcasts on "Botany for the Amateur" made in the United States by Miss Jesse Fiske, State seed analyst of the New Jersey Experimental Station, New Brunswick.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Influence of Substitution on Organic Bond Strength

ATTEMPTS to establish the strength of organic bonds by studying the rate of decomposition of gaseous compounds have been made with success by F. O. Rice[1], but no systematic information on the influence of substitution on bond strength has been obtained. The problem was approached by R. A. Ogg[2] by a study of the breaking of the carbon – iodine bond in various compounds, and the present results were obtained in pursuing the same line by a new method. The vapour of the iodides at low pressure (0·01 mm.) and diluted with a carrier gas (6 mm. nitrogen or hydrogen) was passed through a tube maintained at 300–500° C., and the products were condensed and analysed for iodine and hydrogen iodide.

The assumption from which we started, that the rate-determining process is the unimolecular disruption of the CI bond, was confirmed for ethyl iodide by varying the experimental conditions; in the other cases, however, it could only be shown that the rate of bond breaking was the main factor. Nevertheless, the large variation in the rates of decomposition (10,000 fold at 430°) justifies a comparison of C – I bond strength from the relative decomposition rates. The bond energies tabulated below were calculated from the approximate relationship

$$\log k = -Q/RT + 13,$$

using the values of k for the lowest temperature at which measurement was possible, the other conditions being comparable for all the iodides.

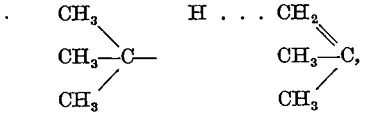
Iodide	Suggested bond energy	
Ethyl	52·5 kcal.	
Vinyl	56·6	Partial double-bond character.
Phenyl	54·0	
Allyl	39·0	Radical degeneracy
Benzyl	44·0	
Acetonyl	45·5	
t-Butyl	45·1	
Benzoyl	44·5	
Acetyl	(50·7)	

Taking ethyl iodide as our zero of reference, we note the manifestation of partial double bond character in vinyl iodide and in phenyl iodide, which is to be explained by a degeneracy of the type[3]

$$H_2C = CH - I \qquad H_2\overset{-}{C} - CH = \overset{+}{I}.$$

On the other hand, benzyl, allyl and acetonyl iodides clearly indicate the degeneracy of the free radical resulting from conjugation of the unshared electron with the double bond or the benzene ring.

These two effects appear to affect jointly the C – I bond in benzoyl iodide which is weakened, but to a lesser extent than in benzyl iodide. The somewhat uncertain value for acetyl iodide may be left undiscussed; but attention should be directed to the strong reduction in bond strength in *t*-butyl iodide. This points to a degeneracy of the free radical of the type



in which the representation containing the double bond is present in nine different forms, as compared with only three forms of this type resonating in the ethyl radical[4].

The magnitude by which the bond strength appears to vary in our experiments is of the order which might be theoretically expected. For example, in the case of allyl iodide and benzyl iodide the resonance energies of the radicals were calculated at 15·4 kcal.[5] and 15 kcal.[6] respectively, while our experiments indicate values of 13·5 kcal. and 9 kcal. The agreement would be improved if the resonance energy of the ethyl radical which might amount to 2-3 kcal. were taken into account.

As regards our absolute values, we note that the average bond energy attributed to C – I of about 45 kcal. is based on a C – H value of about 87 kcal.[7] On the other hand, all estimates agree that the energy required to break the first C – H bond in methane is more than 95 kcal.[8] and that in consequence C – I in methyl iodide is at least 53 kcal. This disagrees with the value of 43 kcal. found by Ogg[9] for methyl iodide, as well as for ethyl and *n*-propyl iodides, and lends support to our result of 52·5 kcal. for ethyl iodide.

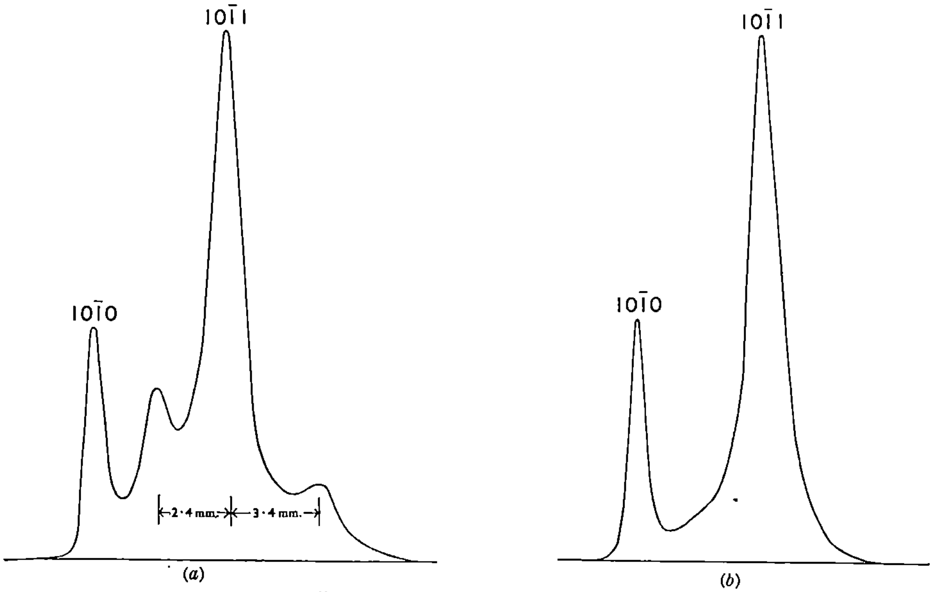
Anomalous Diffractions in the Hull-Debye-Scherrer Spectrum of Graphite

IN the course of an electron diffraction study of several graphites, Finch and Wilman[1] discovered a number of extra diffractions which could not be indexed in the normal way on the basis of the accepted crystal structure of graphite[2]. Of the extra diffractions, two embracing the $10\bar{1}1$ reflexion are clearly observed and cannot easily be accounted for. Because these extra lines occurred with graphites from very different sources, Finch and Wilman concluded that the possibility of impurity could be ruled out. Their main conclusion pointed to the presence of packets of planes with a thickness of 4 unit cells (or 9 layer-planes), in the direction of the c-axis. This would enable lines with fractional l indices to appear, because by analogy with a ruled grating with a few lines, the subsidiary maxima would begin to have the same order of magnitude as the principal diffractions. Thus the lines on either side of the $10\bar{1}1$ would seem to be $10\bar{1}\frac{2}{3}$ and $10\bar{1}\frac{4}{3}$.



MICROPHOTOMETER CURVES, $10\bar{1}0$–$10\bar{1}1$ GROUP, FOR CEYLON GRAPHITE (a) CLEANED WITH HYDROFLUORIC AND HYDROCHLORIC ACIDS, (b) CLEANED WITH HYDROFLUORIC AND HYDROCHLORIC ACIDS, AND 30 HOURS IN CONCENTRATED SULPHURIC PLUS NITRIC ACID MIXTURE.

We have repeatedly observed the extra lines with X-rays using a great variety of natural and artificial graphites. They are *not* a phenomenon entirely associated with the electron diffraction method. With cobalt K_α radiation, a Debye-Scherrer camera 19 cm. in diameter of the Bradley type, and a fine cylindrical specimen 0·3 mm. in diameter, very high resolution of these extra lines is obtained (Fig. a). The fact that all the spectra are reasonably sharp and no cross-grating spectra occur indicates that the graphite crystals are at least of the order of 1,000 A. in size. Careful cleaning of the graphite until the ash was zero failed to influence the intensity of the extra lines, so that the effect of impurity could be discounted. Only a very special chemical treatment affects the graphite. After all the inherent impurities have been removed by the usual methods, the graphite is wet-oxidized in a heated mixture of concentrated nitric and sulphuric acids in a 2 : 3 ratio by volume for 24 hours. This reduces the extra lines to almost zero intensity, but the other spectra remain unchanged (Fig. b). No other acid combination appears to work except concentrated sulphuric acid, which required more than 400 hours to produce the same effect.

The extra diffractions may arise from the dynamic stratification of the crystals in the manner suggested by C. V. Raman and P. Nilakantan[3], who observed extra spectra in the Laue photograph taken along the trigonal axis of diamond. Similar anomalies in Laue photographs have since been reported[4]. The wet oxidation treatment may reduce the size of the crystallites (although still bigger than 1,000 A.) so that the dynamic stratification becomes unstable because of edge effects and the extra lines are unable to appear. To some extent the dynamic stratification is analogous to the static packets of planes 4 unit cells deep as suggested by Finch and Wilman. It would be interesting to see if the dynamic stratification theory can be applied quantitatively to the appearance of these extra Debye-Scherrer reflections.

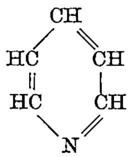
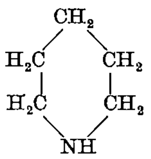
Nature of the Feulgen Reaction with Nucleic Acid

DURING the course of investigations into the probable chemical constitution of the nuclear contents in plants, many observations have been made in addition to the nucleolar staining reaction. Under existing conditions, it seems improbable that a full description of this work can be made for some time, and a note on an apparently significant point is offered here in the hope that it may lead to further useful developments.

The use of the Feulgen nucleal reaction in connexion with cytological technique is proving to be of considerable importance for critical work. It is, of course, well known that this modified Schiff's reaction, now used with such marked success as a selective chromatin stain, is by no means specific for the HC : O group characteristic of aldehydes. While it is generally stated that the colour reaction is due to the available aldehyde group of the aldose in hydrolyzed nucleoprotein, it does not appear to have been previously reported that the leuco-base of fuchsine is also immediately restored to its original colour by such heterocyclic compounds as pyridine and piperidine.

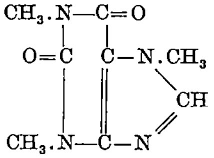


Pyridine

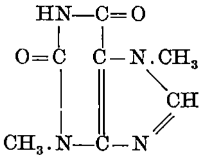


Piperidine

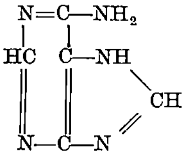
The significance of this observation in relation to the possible behaviour of the purine constituents of nucleoproteins will be at once apparent. Several tests were made on caffeine and theobromine with controls. The typical magenta colour was obtained with these after varying periods of time with different samples and preparations of leuco-base. Caffeine (Kahlbaum) gave a slight magenta colour after 5 minutes and a deep colour after 6 hours; theobromine (B.D.H.) similarly gave a magenta colour after a few minutes, which deepened after standing. It was apparent from this that adenine and guanine should also produce a magenta colour with the fuchsine.



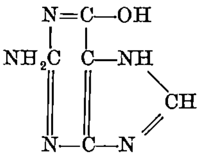
Caffeine



Theobromine



Adenine



Guanine

The probability was tested, using material supplied by the British Drug Houses, Ltd., and positive results were obtained, the characteristic colour appearing after 2–3 hours.

Generally, attention has been given primarily to the pentose constituent of nucleoprotein; but the matter seems to require further consideration. Tests with other components of a nuclear extract may, of course, be affected by the presence of traces of pentose, but the possibility of the reaction with chromatin being given by the purines seems to be strongly indicated by the positive reactions obtained with pure, redistilled pyridine. The peculiar specificity of the Feulgen reaction for the chromatin complex of plant and animal nuclei seems to become somewhat clearer in the light of these observations.

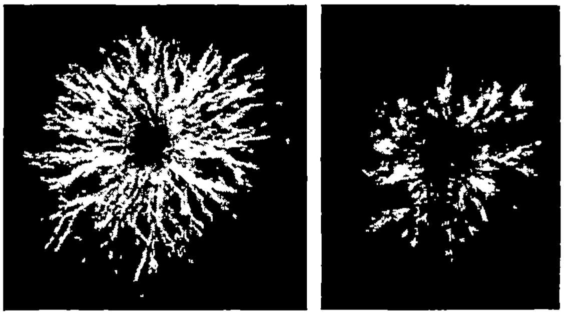
Response of Isolated White Chromatophores of Crustacea to Change of Illumination

It is now generally accepted that the movements of pigment in the light-absorbing chromatophores of decapod Crustacea are controlled by the secretion or secretions of some tissue in the eye-stalks. In addition, many species possess chromatophores which contain a white light-reflecting pigment, the movements of which continue after the eyes and eye-stalks have been amputated. Therefore, it has been suggested that some tissue in the rostral region may affect these white chromatophores, by a secretion which is released in darkness under the control of some exteroceptor other than the eyes[1,2]. However, the results of injection experiments have indicated[3] that the diurnal movements of the white pigment are not under hormonal control, but that the white chromatophores behave as 'independent effectors'[4].



(*a*) (*b*)

(*a*) AN ISOLATED WHITE CHROMATOPHORE OF *Leander serratus*, IMMERSED IN A SOLUTION CONTAINING SODIUM CHLORIDE, CALCIUM CHLORIDE AND EYE-STALK HORMONE, UNDER ILLUMINATION.

(*b*) THE SAME CHROMATOPHORE AS IN (*a*) AFTER ONE HOUR IN DARKNESS.

To test the validity of the latter theory, portions of the carapace of *Leander serratus*, bearing one or two white chromatophores, were immersed in saline media, and examined under various conditions of illumination. Quantitative estimation of the pigment movements was obtained by measuring the diameter of the pigment masses with a micrometer scale. Two measurements were made at right-angles to one another.

In sea-water, isolated white chromatophores attained maximal expansion in a few minutes, but did not afterwards contract when they were placed in darkness. In the body-fluid of *L. serratus*, however, the isolated white chromatophores of this species expanded in light, contracted in darkness and later re-expanded when they were returned to the light. It has been shown[5] that the blood of *L. serratus* is hypotonic to sea-water and has an osmotic pressure which is maintained at a value equivalent to 2·6–2·9 per cent sodium chloride. Therefore, in subsequent experiments, the chromatophores were studied in media which were approximately isotonic to the blood of *L. serratus*.

In a sodium chloride solution the chromatophores contracted in darkness but failed to re-expand under illumination. However, when the chromatophores were placed in solutions containing calcium ions (see

THE CHANGE IN SHAPE OF SINGLE CHROMATOPHORES.

Each reading represents the mean diameter of 6–12 chromatophores. The diameter of each chromatophore was first recorded in light, later after the chromatophore had been one hour in darkness, and finally after the chromatophore had been re-exposed to illumination for one hour.

Medium	Diameter of chromatophores in μ			Percentage contraction	Percentage re-expansion
	Light 1 hr.	Dark 1 hr.	Light 1 hr.		
NaCl (2·7%)	635	508	508	30·9	0
$CaCl_2$ (3·4%)	612	425	537	35·6	19·3
NaCl (2·0%) + $CaCl_2$ (0·85%)	629	316	374	49·7	15·5
NaCl (2·0%) + $CaCl_2$ (0·85%) + eye-stalk hormone	578	316	527	45·5	40·0
Leander blood	1248	749	1105	39·9	32·2
Chromatophores of intact animals	645	305	645	52·5	52·5

table), they contracted in darkness and re-expanded under illumination. The time the chromatophores took to contract when isolated was similar to that taken in the living animal. The addition of small amounts of potassium or magnesium ions did not affect the movements of the white pigment. (The importance of calcium ions in the responses of chromatophores has already been emphasized[6].) The response of the isolated white chromatophores to change of illumination was improved by the addition of a small amount of eye-stalk extract (equivalent to 1/400 eye-stalk per ml.) to the medium. The sensitivity to change of illumination was maintained for a longer period in this way. Even so, the majority of cases the chromatophores lost their capacity to respond after they had been removed from the body for six hours, though in exceptional cases a response was obtained after twenty-four hours.

The white chromatophores of *L. serratus* are therefore independent effectors able to change their shape without either nervous or humoral control.

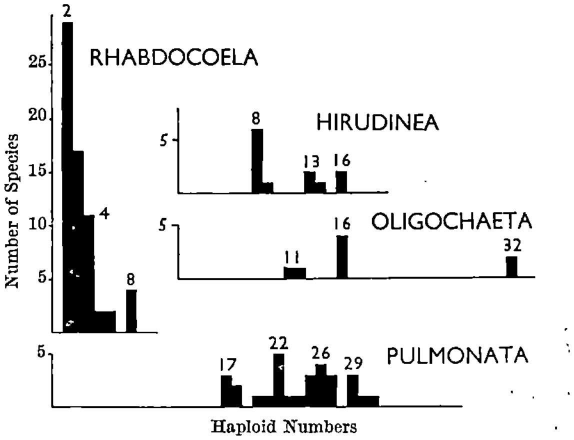
Evidence for Polyploidy in the Hermaphrodite Groups of Animals

IT is now well known that a large number of species of higher plants are polyploids, and it is reasonable to infer that polyploidy has been one of the main evolutionary methods of species formation in the angiosperms. In animals a few instances of polyploidy are known in parthenogenetic forms (for example, in the Crustaceans Artemia[1] and Trichoniscus[2], the moth Solenobia[3] and some of the weevils[4]). Apart from these cases where polyploidy is associated with a complete abolition of the sexual process, there is little evidence for its existence in animals. It was pointed out by Muller[5] that polyploidy could not be expected to occur in groups of bisexual animals, since it would upset the sex-chromosome mechanism. In groups of hermaphrodite animals, however, there seems no *a priori* reason why polyploidy should not be one of the methods of species formation, just as it is in plants. In order to determine whether this is so, I have collected all the available chromosome numbers for the four main groups of hermaphrodite animals (Platyhelminthes, Oligochæta, Hirudinea and Pulmonate Mollusca). After eliminating early determinations which must be regarded as unreliable, the remaining data were plotted in the form of the accompanying histograms. In the case of the Platyhelminthes only the data for the Rhabdocœla were utilized, since very few chromosome numbers are known for the other classes of that phylum.



DATA DERIVED FROM VARIOUS AUTHORITIES

In the Rhabdocœla there is some definite evidence for the occurrence of polyploidy. Thus in the genus Mesostoma one species has a haploid number of 2, six of 4, one of 5 and one of 8. In Phænocora one species has a haploid number of 3 and one of 6. Actually, out of 65 species included in the graph, 17 are possible polyploids, that is, they have haploid numbers which are multiples of numbers known elsewhere in the group. The actual number of polyploid species is probably less than this, since some will have 'multiple' numbers without being polyploids.

In the Pulmonata there is no evidence of polyploidy. Of the 29 species in the graph not a single one could be a polyploid of any other. The only possible exception is *Helix pomatia*; the haploid number of this species was variously stated by the earlier authors as 12, 18 or 24. Actually it seems to be 27, and the early accounts were almost certainly inaccurate[6].

In the Hirudinea and Oligochæta relatively very few chromosome numbers have been determined. In both groups there are two possible polyploids (those with a haploid number of 16 in the Hirudinea and those with a haploid number of 32 in the Oligochæta). Until more cytological work has been carried out on these two groups it would, however, be premature to draw conclusions from the meagre data available.

We must therefore conclude that polyploidy has not occurred in the hermaphrodite groups of animals to anything like the same extent that it has done in most of the families of higher plants. In one group (the Pulmonata) it seems not to have occurred at all, while in the other three it has probably played only a minor role in species formation. It is possible that some special genetical barrier to polyploidy exists in animals; one could imagine that polyploid animals might be less viable than diploids owing to their cell-size being ill-adjusted to the increased chromosome number. Alternatively it is possible that although polyploid individuals may have arisen from time to time, they have not given rise to polyploid races or species owing to the rarity of self-fertilization in hermaphrodite animals. It is worth bearing in mind that in some groups of higher plants (for example, the Gymnosperms) polyploidy likewise seems almost entirely absent.

Practical Science in Schools

I have naturally read with interest the communications from Dr. V. J. Chapman and from the Editors of Nature on this subject.

There is no attempt on my part to get practical work abolished in schools. It is essential for such examinations as the 1st M.B., Higher Certificate and university scholarships. The science specialist should devote, in my opinion, at least half his time to practical work. In so many of our public schools, however, it seems to be felt that if there are about five hundred boys altogether it is necessary to make provision for half of them to do practical work at once. As pointed out by the Editors of Nature a large majority of the boys complete their 'formal' education at the School Certificate stage and for this 'formal' education practical work is unnecessary. Had I my own way, and I am scarcely an anti-science teacher, I would make every boy in a public school learn Latin until he were either fifteen or had passed the School Certificate. Two good science lectures weekly with demonstrations are all that are required. The Latin learnt, however, would be the real thing and not Latin made easy. However, I will not try to dilate on this point.

Dr. Chapman's point about scholarship candidates knowing a good deal of advanced genetics but yet being unable to recognize a twig of larch leaves me almost unmoved. Experienced teachers and examiners will know of hundreds of parallel cases and they really signify nothing. No teacher, let alone the students, will tackle all parts of a vast subject with equal zest. I know of one scholarship candidate who tried to boil shrimps in a thick glass jam-jar, and another who was quite incapable of removing the gelatin from an old photographic negative. The former is a professor and the latter a fellow of his College. Both examiners and teachers might do well to remember such stories, even if they are not true, as that of Sir Isaac Newton who cut two holes in a door, a large one for the cat and a small one for the kitten. Even the greatest sometimes err and are human.

Dr. Chapman's contention that a plant or animal which has been cut up and handled can be more easily remembered, etc., though true, is open to criticism. Direct handling may be essential for the expert, but in general education it is by no means essential nor is it even always desirable. Is it even essential for a gynæcologist to have been a mother?

I certainly find myself at issue with the Editors of Nature when they say it is not the business of schools to train academic, professional and industrial experts but rather to produce intelligent and knowledgeable citizens. The public schools make a great effort to select the very best boys and surely these particular boys should be urged to aim at the very highest standard of attainment and be supplied with the best teaching possible. Really clever boys under the expert teacher should produce a standard of work which will have a tremendous influence on the school as a whole, though obviously no school could cater exclusively for the expert. I think, however, that many public schools, not to mention a few of the universities, might do well to remember sometimes that there is such a thing as a real teaching profession. The primary duty of any teacher is surely to make his students *learn*, and when a student has learnt to teach himself thoroughly he has gone pretty far in the right direction.

The really able boys in a public school are frequently well occupied with classics or mathematics, and even those who wish to specialize in science can often postpone much of their practical work. It is for the second- and third-rate boys who are never likely to get beyond the School Certificate that one apparently requires these palatial laboratories and costly apparatus.

Surely the War should make us reconsider the matter.

A. G. Lowndes.

Plymouth.

Common Salt as a Preservative

With reference to Mr. J. R. Norman's communication from Dr. Paul Chabanaud[1], I should like to support the opinion therein stated as to the value of common salt as a preservative for large specimens or when no other is available.

In the 'twenties I sent to the British Museum (Natural History) from this place, a distance of about 7,000 miles, two or three specimens of *Cephalorhynchus commersonii*, a dolphin 3–4 ft. in length, preserved with this reagent. The abdominal cavity was opened and salt stuffed in to capacity and the whole animal was covered with a heap of salt. Much of the fluid resulting ran away and as much as possible was drained off before packing in still more salt for dispatch. The method proved entirely satisfactory, the first specimen being, I believe, the original of the cast (♂) in the Whale Gallery of the Museum.

Salt was used for the preservation of the female genitalia of *Otaria byronia* illustrated in my recent paper on that species[2]. This specimen was about 14 cm. long and 11 cm. across the cornua and naturally very muscular. It was placed in a glass jar and covered with salt, fresh salt being added to keep the specimen covered as a saturated brine was formed which was poured off. More than a year later the specimen was taken from the salt, soaked in changes of fresh water until quite soft, and then very gradually brought up to alcohol of about 70 per cent. It remained perfectly flexible and was an admirable subject for dissection.

RESEARCH ITEMS

Stone Age Industries in Wyoming, U.S.A.

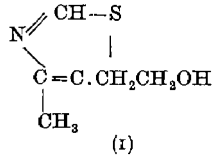
E. B. RENAUD's twelfth report (1940) on the University of Denver Archæological Survey of the High Western Plains deals with the fourth and fifth Denver-Wyoming Expeditions of 1938–39, which were directed to further research work on the stone age industries of Black's Fork Basin in south-west Wyoming. In addition to detailed accounts of field work and sites examined, a report on geological observations in 1938 and a summary of conclusions on the investigation as a whole are here included. Three distinct cultures have occupied Black's Fork Basin at different times and for prolonged periods. (1) The *Peripheral Culture*, of minor importance, sites in south-west Wyoming not being many or abundant in specimens. Though old it cannot be placed exactly in time. The artefacts are of dark chert, small and atypical, and their flaking of indifferent quality. (2) The *Sand Dune Culture* is essentially a camp culture with fireplace, one hand mano, slab metate, arrow-head, but no pottery. It resembles the Camp Culture of the High Western Plains. It is essentially a flake industry, southern and intensive in relation to the Peripheral Culture. (3) The *Typical Culture*, a complex lithic industry of which the component elements have been classified into three chert series, one of moss-agate and one, abundant, of quartzite. Four phases or periods are represented in which the relative number of flakes and unifaces as compared with biface and of sharp with smooth increases in inverse proportion to age. The sites represent extensive and very rich workshops. The artefacts have a distinct palæolithic look and display close similarity with Early and Middle Palæolithic of Europe and Africa. A pebble industry, many *coup-de-poing*-like pieces, and extensive practice of Clactonian flaking are three outstanding features of the industry. Unfortunately there is neither geological nor palæontological evidence to establish age.

Glass-making in Nupe, Nigeria

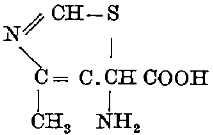
OBSERVATIONS of glass-making in Nupe recorded by Mr. S. F. Nadel (*Man* of June 1940) deal with the work of a guild of glass-makers (*masagá*) who make the real Nupe glass called *bikini* as against that which is obtained by melting down bottles (*kwálaba*). A completely new furnace must be used, not one that has been used for smelting iron. It is circular, approximating 5 ft. high and 2 ft. in diameter. It is covered on top with potsherds and broken calabashes which leave a small gap open. Four men work continuously, working the bellows in shifts, adding fuel, etc. The fire is kept up day and night for from two to five days. The raw material, sand and natron, is first prepared in two heaps in a neighbouring hut. The sand is that dug in making the furnace; the natron is bought from native traders coming down from the Chad. The sand and powdered natron are mixed to a fine powdery mixture, and a little water added to make it of a muddy consistency, the mixture then being placed on the bottom of the furnace. Wood and grass for the lighting of the fire are placed over it and left to burn for 6–7 hours. A little blacksmith's slag is added, washed down by considerable quantities of water. After about 18 hours the glass has become liquid. Samples are taken and after another eight hours the glass is said to be finished. The glass is removed as a red glowing pasty material and left to cool. The glass is stored in this form until required for use in making bangles, when it is melted and worked. In a note by C. G. Seligman it is added that a spectrographic examination by P. D. Ritchie of a mixture of one part of red earth to three of the alkaline product gives a spectrum almost identical with that of the finished Nupe glass and almost identical with that of the red siliceous earth. Only a minute trace of potash is present, the native alkali being essentially sodium carbonate, but containing a fair proportion of calcium. A portion of the mixture heated at 1200° C. for 24 hours produced a glass of poor quality containing nodules of undissolved silica from the red earth and a black glassy matrix resembling the black Nupe glass.

Biogenesis of Vitamin B_1

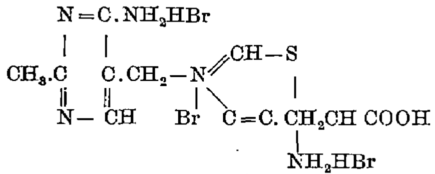
IT is of interest to discover why yeast is able to form such large amounts of B vitamins during its growth, and in particular what are the precursors of and reactions leading to the synthesis of vitamin B_1 (aneurin). C. R. Harington and R. C. G. Moggridge (*Biochem. J.*, 34, 685; 1940) have obtained support for their earlier suggestion that the 4 methyl-5-(β-hydroxyethyl)-thiazole (I) of aneurin might arise during yeast fermentation from α-amino-β-(4-methylthiazole-5)-propionic acid (II) by a reaction analogous to the formation of fusel oil in alcoholic fermentation. The fact that yeast is a rich source of aneurin and is able to effect this type of degradation further supported the hypothesis, and it has been found that the synthetic amino-acid (II) is indeed broken down by yeast to 4 methyl-5-(β-hydroxyethyl)-thiazole.



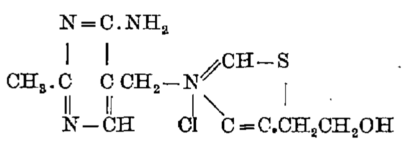
(I)



(II)



(III)



(IV)

The authors are attempting to extend the work by synthesizing the amino-acid (III) analogous to aneurin (IV). If compound (III) could be obtained its fermentation by yeast might be expected to give both aneurin and cocarboxylase (aneurin pyrophosphoric ester).

Ecology of the Estuary of the Aberdeenshire Dee

ALEC MILNE has recently published some interesting observations on ecological aspects of the intertidal area of the estuary of the Aberdeenshire Dee (*Trans. Roy. Soc., Edin.*, 15, Part 1 (No. 4), 1939–40 ; 1940). There is no up-estuary movement (tidal) of the surface layers of water of the Dee, and thus the surface salinity changes due to tidal alterations are less, though the fluctuation at any point in the intertidal area is consequently greater. There are fewer species of the larger animals which are common in the long estuaries, the main reason being the very high salinity fluctuations and the absence of mud flats. The commonest inhabitants are *Jaera marina* and *Gammarus zaddachi*, *Balanus balanoides*, *Procerodes ulvæ* and *Nereis diversicolor* ; *Fucus ceranoides* being the commonest seaweed. Salinity is apparently the chief factor determining distribution in the Dee estuary. There are in the intertidal fauna large numbers of individuals of certain forms.

American Aphids of the Genus Myzus

Miscellaneous Publication No. 371 of the U.S. Department of Agriculture, March 1940, is devoted to an article on this subject by Preston W. Mason of the U.S. Department of Entomology and Plant Quarantine. Several species of the genus are of considerable economic importance, especially in connexion with fruit, market garden and ornamental plants. In addition to the direct injury which they cause to the plants, certain species of Myzus are vectors of virus diseases. Thus *Myzus persicæ* is a known carrier of more kinds of virus diseases than any other species of insect. It is, furthermore, one of the widest distributed of all insects and occurs in all parts of the world where aphid life can exist. *M. convolvuli* has been proved to transmit virus diseases of potatoes, and the new species *M. lilii* is a suspected transmitter of disease among *Lilium candidum*. The article is illustrated by figures showing the diagnostic characters of the various species found in America. Eight of the species dealt with occur also in Europe, and their descriptions, etc., will be found useful in cases of doubtful identification.

Spreading of Spray Fluids

THE wetting and spreading properties of certain spray fluid supplements have been determined by H. Martin (*J. Pom. and Hort. Sci.*, 18, 34 ; 1940). Surface tension, spray retention, area of spread and contact angles on artificial surfaces were determined for twenty different water-soluble products of potential value as spray spreaders. A high degree of correlation was found between advancing and receding contact angles in the case of long-chain compounds, but the correlation was not so close with certain surface-active materials of cyclic structure. Advancing and receding contact angles are distinct entities, the former related to spreading and penetration and the latter determining wetting performance. The area of spread of a liquid droplet is related both to contact angle and spreading coefficient on a given surface, but practical difficulties arise in the use of this as a criterion of wetting and spreading properties. The volume of spray retained under standard conditions on a vertical surface is determined by the receding contact angle, and provides a suitable means of assessing the wetting and spreading properties of both aqueous solutions and heterogeneous spray systems. Chemical analysis, on the other hand, is an unreliable method of assessing spray performance.

Cultural Control of Smut Fungi in Egypt

THE particular methods of cereal culture necessitated by the geographical position of Egypt make possible the control of several smut fungi without the employment of costly insecticides (G. Howard Jones and Abd El-Ghani Seif El-Nasr Eff, "Control of Smut Diseases in Egypt with special reference to Sowing Depth and Soil Moisture", *Min. Agr. Egypt Tech. and Sci. Service Bull.*, No. 224. Cairo : Government Press, Bulâq. P.T.6. 1940). The 'herati' method of sowing in moist soil, and the 'afir' type of planting, where irrigation follows seeding in dry soil, involve differences in the relative depths of sowing, and in the moisture content of the ground. These two factors, with the effect of temperature, appear to control the incidence of flag smut of wheat caused by *Urocystis tritici*, covered smut of barley, *Ustilago hordei*, bunt of wheat, *Tilletia fœtens*, and grain smut of millet and broom corn, *Sphacelotheca sorghi*. The relatively long passage of a coleoptile from deeply sown grain through moist soil apparently gives more chance of infection than the quick shoot emergence from shallow sowings in drier soil. Infection is much greater when the average ground temperature for ten days after planting lies between 13° and 17° C. Practical suggestions for new methods of sowing are made (see also NATURE, 142, 917 ; 1938).

Genetics and Long-day Plants

T. M. Little, J. H. Kantor and B. H. Robinson (*J. Hered.*, 31, 73–77) show that virescent foliage and early flowering in the African marigold (*Tagetes erecta*) are both inherited as Mendelian recessives. The virescent character is pronounced under temperatures between 55° and 75°, but when hotter conditions are present the virescent plants can scarcely be distinguished from normal. But low temperatures alone will not permit the expression of the character since it is found that the virescent character does not appear in plants grown near the United States–Mexican border, where the temperature ranges from 32° to 70°, but the day is shorter. Early flowering is not influenced by temperature, but length of day greatly affects the character. In winter, all plants come into bloom in eleven weeks, but in spring normal plants take seventeen weeks to flower while the early flowering strain takes twelve weeks.

Selective Fertilization in the Raspberry

D. LEWIS (*Genetics*, 25, 278–286 ; 1940) shows that a gene w inhibits and severely retards pollen-tube growth in the raspberry. w is linked with t and g which are also in the same linkage group as b and x. The order of the genes is B, T, G and W. It was found that the single factor ratios of $T : t$ and $G : g$ were frequently distorted as the result of the linkage with $W : w$.

Genetics of Awns in Triticum

A. E. Watkins and S. Ellerton (*J. Genetics*, 40, 243–270 ; 1940) discuss the literature and give results of their experiments on the inheritance and behaviour of awns in wheat. They show that hexaploids usually have shorter awns than tetraploids and that there are both major and modifying genes which affect size of awn. Beardless is the bottom recessive character as compared with tipped-1, B_1, half awned b_1^a, B_2, half awned A and hooded Hd. B_1, b_1^a, and b_1 are allelomorphic with one another, while B_2 A and b_2 may also be multiple allelomorphs. The genes B_1, B_2 and Hd may be transferred to tetraploid wheats and there segregate regularly. B_1 is linked with pubescent node, square-headedness, and keeled glumes.

Plasticity Conditions for Fault Formation

A VERY valuable mathematical paper on plasticity conditions requisite for the formation of normal and reverse faults has been written by Katsutada Sezawa (*Bull. Earthquake Res. Inst., Tokyo*, **17**, Part 4, 661–674; 1939). Three idealized models were chosen: (1) spherical, (2) cylindrical, (3) plane. Sezawa inferred that when the liquid earth partly solidified, the solidified parts changed from incompressible to compressible. If there were no faults in the earth, the lateral compression in any particular place would exceed the vertical, thus giving rise to reverse faults. With the aid of mathematical plasticity the direction of the fault causing stress is obtained. On the maximum shear stress theory the inclination of the reverse fault would be 45° to the horizontal, but owing to frictional force on the sliding surface the theory has to be modified and the angle is likely to be only 10° or 20°. When the solidified earth has faults, the stress conditions are different. The plastic state is nearly the same as that of the earth with a plane surface. The horizontal compression is less than the vertical, and the formation of normal faults is highly probable. Owing to frictional force on the sliding surface, the inclination of normal faults to the horizontal is more than 45°, say 60°. Sezawa infers that it is probable that such fault surfaces as lie near so large a trench as the Japan Trench are reverse faults, which were formed at a very early stage in the life of the solid earth. The usual smaller faults on land would be normal faults formed at a relatively later stage in the history of the solid earth. It is possible that deep-focus earthquakes are in some way related to reverse faults, and in the present state of the earth's crust, plastic stresses causing reverse and normal faults might still remain.

Thunderstorms at Karachi

DURING the past three years, the study of the thunderstorms at Karachi has been followed by B. N. Desai and S. Mal, of the India Meteorological Department. Their work was first introduced to English meteorologists in a paper entitled "The Mechanism of Thundery Conditions at Karachi" (*Q. J. Roy. Met. Soc.*, **64**, 525–37). Owing no doubt to the reorganization of the India Meteorological Department, more than two years have elapsed between the time when the material of their latest paper was first communicated to the Department, and its appearance as "A Discussion of Some Aeroplane Ascents at Drigh Road (Karachi) on days of Dust Storms, Thunderstorms and Dust-Raising Winds" (*Sci. Notes India Met. Dep.*, **8**, No. 87). The observations made during these aeroplane ascents are set out on the now familiar tephigram system, both dry- and wet-bulb readings being plotted. It appears that the knowledge about latent instability of the atmosphere gained from early-morning ascents was not always found to be sufficient for the prediction later in the day of dust-raising winds owing their origin to thunderstorms, and that for this purpose the weather of surrounding regions had to be taken into account. A distinction is drawn by the authors between thundery conditions that do not result in winds of Beaufort force 6 or more, and conditions which do give such winds, because of the importance for aviation of knowing whether a dust haze or dust storm is likely to develop. There does not appear from this work to be any fundamental difference between the incidence of thunder in the peculiarly damp and enervating climate of Karachi and its incidence in a bracing climate like that of, say, East Anglia. In both regions strong thunder squalls are far more likely when the thunder is associated with winds of widely different origin than when there is only the local development of instability from unequal heating within a single air mass.

Chlorine Monoxide and Water

IT is known that chlorine monoxide dissolves in water to form hypochlorous acid, but no solid hydrate was known. C. H. Secoy and G. H. Cady (*J. Amer. Chem. Soc.*, **62**, 1036; 1940) have prepared pure chlorine monoxide (made by the action of chlorine mixed with air on yellow mercuric oxide) and find the freezing point of a freshly prepared sample, dried by passing the gas over phosphorus pentoxide, to be – 120·6°. The compositions of saturated solutions in water (20·7 mol per cent at 236·8° K. to 22·9 mol per cent at 263·8° K.) were determined. Chlorine monoxide and water form a pair of partially miscible liquids. The solid phase formed from solutions of concentration greater than 11·7 mol per cent was found to be the crystalline dihydrate of hypochlorous acid, $HOCl, 2H_2O$.

Dipole Moments and Structures

MEASUREMENTS of the dipole moments of hydrogen disulphide, sulphur monochloride, selenium monochloride, selenium oxychloride, phosphoryl chloride and thiophosphoryl chloride in benzene or heptane (C. P. Smyth, G. L. Lewis, A. J. Grossman and F. B. Jennings, *J. Amer. Chem. Soc.*, **62**, 1219; 1940) have been used to obtain information of structures. H_2S_2 may be explained by H—S—S—H, but better if a small proportion of branched molecules H_2S—S are present. S_2Cl_2 and Se_2Cl_2 may be explained with difficulty by Cl—S—S—Cl and Cl—Se—Se—Cl, but better by branched structures S—SCl_2 and Se—$SeCl_2$ in the form of an irregular tetrahedron, or a mixture of extended and branched structures. The values for the moments of the bonds calculated are: SeO in $SeOCl_2$, 3·0; $\overset{+}{\mathrm{P}}—\overset{-}{\mathrm{O}}$ in $POCl_3$, 3·5; $\overset{+}{\mathrm{P}}—\overset{-}{\mathrm{S}}$ in $PSCl_3$, 2·5. The third is lowered to a greater extent by induction than the second.

Sunspots during 1937

THE Astronomer Royal has discussed the mean areas and heliographic latitudes of sunspots during 1937 (*Mon. Not. Roy. Astro. Soc.*, **100**, 6; April 1940). The results are in continuation of those given in *Mon. Not. Roy. Astro. Soc.*, **98**, 425 (1938), and are derived from the measurement at Greenwich of photographs taken at the Royal Observatories of Greenwich and the Cape and at the Kodaikanal Observatory, India. They are summarized in four tables, and it is interesting to notice that on no day in the year 1937 were sunspots and faculæ absent from the sun's disk. For the first three years of the present cycle, the southern hemisphere was the more active, but during 1937 the northern hemisphere showed more activity, the ratio of the mean daily area of sunspots, north and south of the equator, being 1·7 : 1. The mean latitudes of all spots, weighted according to the area, is 17·02°, which is 3·3° nearer the sun's equator than in 1936.

DETERMINATION OF THE SIZES OF VIRUSES AND GENES BY RADIATION METHODS

By D. E. LEA,
STRANGEWAYS RESEARCH LABORATORY, CAMBRIDGE

IT has been shown recently that viruses[1,2] and phages[3] are inactivated by exposure to ionizing radiations, that is to X-rays or the various radiations from radioactive substances. It appears that the inactivation process is of a particularly simple and direct type, a single ionization or cluster of ionizations being capable of inactivating a particle of the phage or virus.

Two lines of evidence lead to this conclusion. In the first place, if the size of the virus particle is approximately known, and if the dose of radiation needed for inactivation is expressed in terms of ionizations per cm.³ in the biological material, it is found that this dose corresponds, at any rate in order of magnitude, to one ionization in a volume equal to the volume of the virus particle.

The second argument is more precise though less direct, and is based on internal evidence from the radiation experiments themselves. These show that the effect of a given *dose* of radiation is independent of the *intensity* at which it is delivered, and further that the inactivation process follows the law of a monomolecular reaction, that is, the proportion surviving diminishes exponentially with the time for which the radiation acts. These experimental facts indicate that the inactivation is of the nature of a single unit process, the line of argument being one familiar in radiobiology (see for example refs.[3,4,5,6,7]).

The possibility is thus presented of using the radiation experiments as a means of determining the size of the virus particles. If the inactivation dose, that is, that dose leading to reduction of the proportion surviving to e^{-1}, is n ionizations per cm.³, then one would argue that the volume, v, of the virus is given by the equation $n = 1/v$. Certain complications involving the spatial distribution of the ionizations lead to some modification of this simple relation. In the first place, ionizations occur in small clusters, sufficiently compact to behave as single units and averaging 3 ionizations per cluster, so that the inactivation dose becomes $3/v$ ionizations per cm.³. These clusters of ionization are distributed along the paths of ionizing particles which travel in approximately straight lines through the material, and in some cases the separation of the clusters is small, so that an ionizing particle which passes through a virus particle inevitably leaves several clusters of ionization in it. If the mean number of clusters left in a virus by an ionizing particle which inactivates it is F, then the inactivation dose becomes $3F/v$ ionizations per cm.³ F clearly depends on the diameter of the virus ($2r$) and the mean separation (L) of consecutive clusters along the path of the ionizing particle, and may be calculated[5].

I quote in Table 1 a recent experimental determination by Wollman, Holweck and Luria[3] of the inactivation doses of phage 16 for three different radiations, and deduce for each the value of $2r$, the diameter of the phage particle, which would make the experimental inactivation dose equal to $3F/v$. To obtain the doses in ionizations per cm.³ from the measured doses in roentgens the latter are multiplied by a factor which varies a little for different radiations depending on the relative absorption of tissue and air, the extreme values being $2 \cdot 6 \times 10^{12}$ for α-rays and $1 \cdot 3 \times 10^{12}$ for soft X-rays.

TABLE 1. RADIATIONS ON PHAGE 16

Radiation	X-rays (0·15 A.)	X-rays (0·71 A.)	α-rays
Ion clusters per cm.	$2 \cdot 1 \times 10^5$	$3 \cdot 3 \times 10^6$	$1 \cdot 5 \times 10^7$
Value of F	1·44	1·82	85
Inactivation dose (ions per cm.³)	$6 \cdot 7 \times 10^{16}$	$6 \cdot 0 \times 10^{16}$	$7 \cdot 9 \times 10^{17}$
Diameter of phage	50 mμ	56 mμ	85 mμ

The estimate of the diameter of the virus from ultra-centrifugation and ultra-filtration experiments is quoted by the authors as 50–75 mμ, which is seen to be in agreement with the values deduced from the radiation experiments.

Table 2 shows some preliminary results[2] on the inactivation of tobacco necrosis virus by X-rays, which have been used in a similar manner to determine the diameter of the virus. The diameter deduced from ultra-filtration experiments[8] is 12–20 mμ, and this value is seen to be in good agreement with the values derived from the radiation experiments.

TABLE 2. INACTIVATION OF TOBACCO NECROSIS VIRUS

Radiation	X-rays (1·5 A.)	X-rays (8·3 A.)
Ion clusters per cm.	5×10^5	$2 \cdot 4 \times 10^6$
Value of F	1·40	2·60
Inactivation dose (ions per cm.³)	$1 \cdot 2 \times 10^{18}$	$6 \cdot 1 \times 10^{18}$
Diameter of virus	19 mμ	14 mμ

In the examples so far cited the knowledge of the inactivation dose to any one radiation suffices to determine the size of the virus or phage concerned, and the use of several different radiations merely serves for confirmation. We come now to consideration of a more complicated case, in which the comparison of the effects of two radiations of very different ionization density is the essential experimental datum. In experiments on the production of sex-linked recessive lethal mutations in Drosophila by irradiation of the sperm, the effect observed is due to the inactivation by the radiation of any one of the large number (N) of genes in the X-chromosome capable of being modified in this way, and since N is not known (except as to order of magnitude[9]), observations of the production of lethals by one radiation does not enable the gene size to be determined. However, the ratio of the doses of two different radiations required to produce the same percentage of lethals does not involve N, but only the ratio of the values of F for the two radiations. Since the quantity F depends on the diameter of the gene, this last may be calculated. In Table 3, it is shown that the experimental results with three different radiations may be satisfactorily fitted by assuming that there are 1,860 genes in the X-chromosome having an average diameter of 3·78 mμ.

TABLE 3. SEX-LINKED LETHAL MUTATIONS IN DROSOPHILA

Radiation	X-rays	Neutrons	α-rays
Ion clusters per cm.	2×10^{5}	$3·7 \times 10^{6}$	$1·6 \times 10^{7}$
Value of F	1·03	1·60	4·3
% mutations per 1,000 r, calculated	2·89%	1·86%	1·08%
% mutations per 1,000 r, experimental	2·95%[4]	1·85%[10]	0·84%[11]

While these figures are to be regarded as preliminary in view of the fact that N in particular is very sensitive to any error in the experimental determination, it is likely that the radiation method will, with sufficient experimental precision, become the best method of determining the size and number of genes in Drosophila. $2r$ is, of course, strictly the diameter of the region or 'target' associated with a gene within which an ionization must be produced to cause a mutation of that gene. The closeness of the correspondence between the size of the target and the size of the biological entity in the case of the phage and virus work makes it probable, however, that the distinction between the size of the gene and the size of the target is not an important one.

Besides the inactivation of viruses and the production of gene mutations, there are other biological actions of radiation which have been interpreted in terms of the existence of 'targets' or regions of special sensitivity in the organism. It is probable that in some of these cases this interpretation is unsound, in others the size of the target has been incorrectly deduced owing to data not being available for a sufficient number of different radiations. The lethal action of radiations on bacteria, which has been investigated by many authors, provides a case in point. In the past it has been usual to assume that the target in this case consists of a single sphere, and estimates for its diameter of the order of a few tenths of a micron have been given[7,12]. When data are available, however, for a number of radiations covering a sufficiently wide range of ion density, it appears that the assumption of a single large spherical target cannot be made to fit the results, but the assumption of a large number of small spherical targets is more successful. It appears highly probable that the lethal effect of radiations on bacteria is to be interpreted as the production of lethal mutation, there being a large number of genes in the bacterium any one of which inactivated prevents the organism from developing into a visible colony when plated out. In Table 4 theoretical estimates of the lethal dose for *Bact. coli* are calculated by the same procedure as was used for the calculation of gene mutation production in Table 3, it being assumed that the organism contains 1,150 genes of diameter 8·6 mμ.

TABLE 4. LETHAL MUTATIONS IN *Bact. Coli.*

Radiation	β- or γ-rays	X-rays (1·5 A.)	X-rays (8·3 A.)	α-rays
Ion clusters per cm.	3×10^{4}	5×10^{5}	$2·4 \times 10^{6}$	$1·3 \times 10^{7}$
Value of F	1·01	1·16	2·00	7·65
Mean lethal dose in r, calculated	$4·6 \times 10^{1}$	$6·9 \times 10^{3}$	$10·3 \times 10^{3}$	23×10^{3}
Mean lethal dose in r, experimental	$4·6 \times 10^{3}$ [7]	$6·5 \times 10^{3}$ [13]	$7·5 \times 10^{3}$ [13]	24×10^{3} [7]

While the radiation method has so far had a relatively limited application, enough examples have been given above to indicate that it is a powerful tool for the investigation of biological entities of subcellular size.

FRICTION AND SURFACE FINISH

By Prof. Jerome C. Hunsaker,

Massachusetts Institute of Technology

CONFERENCES on Friction and Surface Finish were held at the Massachusetts Institute of Technology during June 5–7 under the joint auspices of the Departments of Mechanical Engineering and Metallurgy. Representatives of the automobile, aviation, oil, machine tool, grinding, general machinery and other industries took part. The object of the Conferences was to bring before engineers associated with the many industries concerned, a summary of present knowledge regarding friction and finish, and to bring out by discussion an appreciation of what new information is needed and an indication of the most promising directions for future research. The discussion was too extensive to report here, but the following notes indicate matters which were especially interesting to those present.

A. F. Underwood (General Motors Research Laboratories) reviewed the general problem of fluid and boundary lubrication from the automobile engineer's point of view. He discussed the current practice of surface preparation of bearings, pistons, cylinders, cams and gears, and pointed out that the metals that make good bearing materials all lie in certain specific parts of the periodic table. The failure of bearing metals through fatigue was also discussed.

John Wulff (M.I.T.) has determined, by means of electron diffraction studies of the ferrite induced by cold work in 18–8 stainless steel, the depth of disturbance in a metal produced by various methods of surface finishing. The disturbance due to wet or dry grinding goes much deeper than that due to lapping or super-finishing.

Aspects and problems of lubrication and surface finish peculiar to the aircraft industry were discussed by Leonard Hobbs (Pratt and Whitney Aircraft), and D. A. Wallace (Chrysler Corporation) described the method of super-finishing and cited examples of improvement in operation of automobiles obtained thereby.

J. T. Burwell (M.I.T.) reported on the effect of surface finish on the metal worn off a journal during 'running-in' and also its effect on the friction coefficient and load capacity of a journal bearing. He finds that the load capacity increases and the minimum coefficient of friction decreases with increasing surface smoothness.

David Harris (Gillette Razor Company) discussed the surface finishing of razor blades, and described a machine for grading bonded abrasive stones and wheels.

Stewart Way (Westinghouse Research Laboratories) described the various methods of describing and measuring surface profile. These include cutting and polishing a section, optical methods, and mechanical methods. The errors and limitations of each method were discussed; none is good for measuring profiles of which the maximum deviation from a median plane is less than 10 micro-inches. H. R. Nelson (Battelle Memorial Institute) described a technique for describing surface profiles by means of nickel plating the surface and then grinding and polishing a section at an angle of 2° with the surface. The borderline in this section between the nickel plate and the specimen is a twenty-five fold magnification of the actual profile. The whole can then be photomicrographed at any additional magnification desired.

Hans Ernst and M. E. Merchant (Cincinnati Milling Machine Co.) proposed an expression for the friction coefficient between rubbing surfaces:

$$\mu = \frac{S}{H} + \tan\theta,$$

where S is the shear stress of the weld formed between the two surfaces, H is the hardness of pressure of fluidity of the weaker, and θ is the average slope of the surfaces. The first term accounts for the molecular adhesion in surface friction and the second term for the interlocking of asperities. Experiments conducted on dry, clean surfaces in a vacuum substantiate this formula.

Otto Beeck (Shell Development Company) described friction measurements using the four-ball machine of Bourlage on E.P. lubricants and also electron diffraction studies of the surface films produced by these lubricants. He finds a constant coefficient of friction below a certain critical speed for these lubricants and suggests calling this the region of boundary lubrication. The action of most E.P. lubricants is to form a metal phosphide, arsenide, etc., the eutectic mixture of which with the metal has a much lower melting point with resultant decreased resistance to shear. R. W. Dayton (Battelle Memorial Institute) described various laboratory methods of measuring wear between rubbing metal surfaces. He stated that wear due to mutual abrasion of rough surfaces is not very common, and showed that even very small amounts of adventitious dirt in a lubricating oil can greatly increase wear. He also discussed failure of bearing metals through fatigue.

O. R. Schurig (General Electric Company), who reviewed the course of the conference, emphasized that the degree of smoothness of a rubbing surface should depend entirely on the use to which it is to be put. He stated that the load capacity of a sand-blasted surface as measured in an Almen testing machine is greater than that of a fine-ground surface.

F. Morgan (Gulf Research Laboratories) described a repetition of Bowden's experiments measuring the temperature flash during the 'slip' portion of a 'stick-slip' cycle and stated that for moderate speeds a temperature rise of only 30° C. could be observed in contrast to Bowden's observation of several hundred degrees rise.

W. E. Campbell (Bell Telephone Laboratories) reported on measurements of static friction between dissimilar dry metal surfaces. He has obtained good agreement with the results of Ernst and Merchant. He finds that the presence of moisture in the air raises the static coefficient of friction, and the presence of water in a lubricant also does the same thing.

ANAEROBIC DEGRADATION OF CYSTINE AND CYSTEINE

THE bacterial degradation of cystine and cysteine under anaerobic conditions with liberation of hydrogen sulphide and ammonia has recently formed the subject of interesting papers by Desnuelle, and by Desnuelle, Wookey and Fromageot. The former author worked with suspensions of non-proliferating *B. coli*[1], whereas the latter authors used suspensions of propionic acid bacteria[2]. A systematic study by Tarr[3] of the production of hydrogen sulphide by washed bacterial suspensions showed that cysteine and cystine are decomposed anaerobically by numerous bacteria with formation of hydrogen sulphide. Desnuelle and Fromageot[4] pointed out that a specific enzyme which they termed cysteinase was responsible for the breakdown of the amino acid.

The results with *B. coli* now indicate that the following changes take place in the anaerobic breakdown of cystine:

1. $l(-)$ cystine + $DH_2 \rightarrow 2l(+)$ cysteine + D.
2. $2l(+)$ cysteine $\rightarrow 2H_2S + 2NH_3$ + other products.

Process (1) involves the co-operation of a hydrogen donator DH_2 whilst process (2) is catalysed by cysteinase. The presence of glucose, and to a less extent fructose, greatly accelerates the formation of hydrogen sulphide from cystine; these sugars acting apparently as hydrogen donators. The presence of molecular hydrogen does not markedly affect the process, though it is known that *B. coli* is able to activate molecular hydrogen as a hydrogen donator. The presence of formate, which is a most vigorous hydrogen donator in presence of *B. coli*, has the remarkable effect of inhibiting the formation of hydrogen sulphide from cystine. The process of breakdown of cysteine or cystine by *B. coli* seems to be confined to $l(+)$ cysteine and $l(-)$ cystine.

Results with resting propionic acid bacteria also show an accelerating effect of glucose on the anaerobic formation of hydrogen sulphide from cystine, but the kinetics of the reaction differ from those obtained with *B. coli*. There is not the rigid optical specificity of reaction which takes place in the case of *B. coli*, and both *l*- and *d*-cysteine are equally well attacked. Ammonia formation does not proceed parallel with that of hydrogen sulphide; in fact, in the presence of glucose, which accelerates hydrogen sulphide production, ammonia formation is greatly retarded. Both alanine and pyruvate inhibit the anaerobic breakdown of cysteine by suspensions of propionic acid bacteria.

POPULATION PROBLEMS IN INDIA

THE second Indian Population Congress was held at Bombay in 1938 and its results are now published in a large volume*. Practically every aspect of the population problem is examined, with special reference to India. The numerous papers, many of them by men and women of high attainment and expert knowledge, show an increasing interest in what is probably India's greatest problem.

Among the topics considered are birth control, problems of sex, housing, vital statistics, infant mortality, the logistic law of population growth, optimum population, poverty, employment, nutrition, fertility, the primitive tribes, and marriage registration. Widely different views are expressed regarding the nature of the over-population problem in India, a few claiming that it does not exist. But most writers recognize that a serious problem needs to be faced without delay.

It is impossible to quote from such an extensive series of essays, but it may be worth while setting down a few of the relevant facts. In the 1931 census 73 per cent of the people lived by agriculture; yet with a population now probably 377 millions and an annual increase of 3·5 millions, the increase in rice production in the period 1910–35 is only 6 per cent and wheat shows a steady decline. The infant mortality is 232·6 per 1,000 and the maternal mortality 24·5 per 1,000, or six times that of England and Wales. The pressure of population is indicated by the statement that the average length of life has declined from 30 in 1881 to 23 in 1931. In every 1,000 persons, 10 are suffering from night-blindness, 6 from rickets and 4 from tuberculosis. It is claimed that India only produces 75–83 per cent of its food requirements in calories.

On the other hand, it is pointed out that there is differential fertility within the population as regards both classes and tribes. The 1931 census listed 25 million primitive peoples of many types, some of whom, such as the Todas, Kotas, Gonds, Bhils and Angami Nagas, have shown a marked decline in numbers. The process of transforming primitive tribes into Hindu castes goes on, but some of them at least continue to decline in numbers after being Hinduized. These tribes still constitute 8 per cent of the population of India.

It is clear that Indian politicians will find plenty of scope for their energies when they begin to consider seriously the vital problems of population and nutrition in India.

POTENTIAL AND REAL SCIENTIFIC MAN-POWER

THE various reports which have already been issued by the Select Committee on National Expenditure have afforded encouraging evidence of a more scientific outlook in the prosecution of our war effort, though there is still room for improvement in attempts to get the maximum utilization of scientific knowledge and resources in the elaboration of policy and in its execution. The eighth of these reports, which comes from the sub-committee on Home Defence Services, deals with matters with which scientific workers are themselves directly concerned.

The first and major of these subjects is the Central Register, which originated as a part of the National Service campaign, the establishment and working of which are critically reviewed. The Register was compiled through the medium of the professional and technical institutions, which circularized their members with an appeal issued on behalf of the Minister of Labour and National Service. In addition, individual applications for enrolment on the technical section of the Register were examined by the committees, and the volunteers were enrolled if found suitably qualified. Applications for enrolment on the administrative and business management sections of the Register were examined by the Department on the basis of standards laid down by the Administration and Management Committee.

Altogether about 50,000 individual applications for enrolment in the Register have been examined since the outbreak of war, of which somewhat less than half have been accepted. On May 20, the live section of the Central Register contained 97,044 names, sorted into 75 main classifications and 735 sub-classifications.

The Central Register is thus an essential part of the organization of the national effort. The report emphasizes, however, that it is not, as is often supposed, an organization for finding jobs for men but for finding men for the jobs. There are still many people of the highest qualifications who appear not to have realized this and have failed to register. The recent order of the Minister of Labour and National Service regarding the compulsory registration of professional engineers, while an indication that registration of engineers is incomplete, is not to be taken as implying greater backwardness on their part than with other scientific and technical workers. It was the first and essential prelude to any considerable use by the Minister of Labour of his wide powers of transference and placing of labour of all kinds, whether professional or otherwise. The order is expected to add about 30,000 to the 20,000 names already appearing in the engineering categories of the Register.

The subsequent extension of compulsory registration to chemists, physicists and quantity surveyors shows that the Minister of Labour has lost little time in acting on the sub-committee's recommendation that complete, and therefore compulsory, registration of persons in categories which are, or are likely to become, scarcity categories of the Central Register is essential. No organization of priority is possible without this foundation.

The report's major criticisms are indeed in respect of this question of priority and of the use made of the Central Register. In regard to the first point, there has until recently been no effective machinery for determining labour priority. Obviously the ultimate decision whether to release a man or woman of the Central Register standard from his or her appointment can no longer be left with the employer. Compulsory registration is a first step to this end; but the report also points out that the effective placing of scientific or technical staff in industries subject to the Undertakings (Restriction on Engagement) Order, 1940, can be exercised through the Central Register better than through the local office.

Hitherto the main use of the Central Register has been by Government departments and by such bodies as Chatham House and the British Council. This position has led to the erroneous belief that the Central Register is intended to divert highly qualified persons into the Departments rather than into vital war and export industries. The declared object of the Register is to supply additional wartime needs, whether in Government departments or elsewhere, and the sub-committee's recommendations in regard to wider use of the Register are designed to ensure that it plays much more effectively its essential part in the organization of the war effort.

The report recommends accordingly that industrial undertakings under Government control should be immediately and strongly recommended to recruit technical and professional staff from the Central Register. It further recommends that the rule that Government departments should recruit temporary staff of Central Register standards solely through that Register should be strictly enforced, except where it is urgent that the post be filled immediately and where the post to be filled is of a character requiring special qualifications and for which there is a limited field of choice. Even in regard to the latter reservation, it may well be held that use of the Central Register is the more appropriate method, particularly if professional institutions, which in normal times maintain their own appointments bureaux for the benefit of qualified members, maintained sufficiently close contact with the Central Register.

The report undoubtedly implies that more whole-hearted support should be given to the Central Register by individual scientific workers and their professional associations. More specifically, however, it urges that Government departments should assist the Central Register to function more effectively by presenting their demands for technical staff through a technical rather than an establishment officer, to secure the more precise formulation of their requirements. Similarly it is recommended that they should not require full technical qualifications for posts which are primarily administrative, and that they should not be too rigid in their requirements in regard to age. Expediting the notification of appointments is also urged as facilitating the work of the Register.

The report also comments on the inadequate salaries frequently offered and on the absence of any provision for registering firms of technical consultants, who might be willing to work together as a team. Such teams, accustomed to work together and possessing varied qualifications and experience, would often be likely to be more effective than a technical section of a Government department built up piece-meal. The sub-committee strongly recommends the careful exploration of this source of technical and professional skill at present untapped by Government departments and industries in the war effort.

Obviously a number of these recommendations and suggestions, although addressed primarily to Government departments, merit equally careful consideration by industry if the Central Register is to make its full contribution to our war effort. Moreover, many individual scientific workers are themselves occupying positions of responsibility which enable them to implement such findings, and it may well be hoped that the appearance of this report will lead them to consider very closely the possibilities of thus implementing the co-ordination of our resources of scientific and technical knowledge and skill.

The observations of the report on the neglect of the Central Register of Aliens appear at a time when renewed attention has been directed to the use generally of the services and special knowledge of friendly aliens and refugees in our midst. Both in the Houses of Parliament and in the general Press, the general internment of aliens has received strong criticism even from those who are most fully alive to the necessity of the policy of internment as such.

The question has come into prominence from two points of view; first in view of its damaging effects on the war effort, and second, from its effect on opinion abroad, alike in providing material for enemy propaganda, in neglect to use those who could be of service to our own cause in that field, and as inconsistent with our traditions and the ideals for which we are fighting. It is, of course, with the first of these alone that the sub-committee's report is concerned.

The Central Register of Aliens has been compiled mainly through the medium of the Society for the Protection of Science and Learning and the refugee agencies dealing with professional classes. It is largely confined to the scarcity categories of the main Central Register. The qualifications of these aliens are carefully examined, with the assistance of the chairmen of committees, before they are enrolled. The aliens registered are either friendly aliens or, if enemy aliens, those remaining in Category C (exempted from all restrictions), where they have been placed by the Home Office tribunals.

The sub-committee was informed that, in general, resort is only had to the Aliens Section of the Central Register to fill those vacancies for which aliens would naturally be expected to be useful, or vacancies in scarcity categories The sub-committee is satisfied that this Register could perform useful service. It contains a wealth of valuable material, including names of international repute. Demands on this section of the Register should not be hindered merely by the failure to devise such safeguards as may be required on grounds of security.

The hope thus expressed by the sub-committee will be echoed by every scientific worker. As pointed out in a recent leading article (NATURE, 145, 796; 1940), any form of preferential treatment of alien scientific workers would carry with it a grave element of risk which could not be justified. While, however, general internment of alien men of science may have been necessary at the time it was carried out as a precautionary measure, neither in science nor in other fields have we such a superabundance of man-power or brains that we can neglect any source of assistance. This was visualized as a possibility in the same article in NATURE. Repeated instances have already been cited in Parliament and in the Press of the actual interruption of war-work through indiscriminate internment of friendly and anti-Nazi aliens, apart altogether from the refusal to accept offers of service from those only too eager to help.

There is little reason to doubt that the actual conditions in the internment camps will speedily be improved, but beyond this a definite aliens' policy is wanted, the absence of which is largely responsible for the worst mistakes or abuses. An aliens' board or commission under a responsible minister is required to supervise the whole problem, look after the welfare of aliens, examine and re-examine their credentials, and use to the full the abilities of those it finds trustworthy. Such an authority might well have prevented the scandals of recent weeks. It should prove the most effective means of implementing the recommendation of the report of the Select Committee and making available for the war effort here and in the overseas Empire the skill, knowledge and good will of many whose services are at present denied to us only by our own policy.

The vigour with which the Minister of Labour and National Service has already acted on other recommendations of the Select Committee, no less than the terms of the appeal addressed to the management of all the 9,000 firms working for the Government by the First Lord of the Admiralty, the Minister of Supply, and the Minister of Aircraft Production, will encourage the hope that this matter will not be overlooked. Sir John Anderson has now announced in the House of Commons on July 23, among other important changes in the treatment of enemy aliens, the formation of a small advisory committee to assist him in considering the question of enlarging the categories of exemption to include particularly those who could render services of special value or make a significant contribution to the war effort. This, with the transfer to the Home Office of the responsibility for managing internment camps, should go far to facilitate the rectification of mistakes, and the new policy has already been warmly welcomed.

Rapid progress should now be made in releasing those who have been wrongfully interned and in making life tolerable for those still confined. At the same time the new policy will still exclude numbers of potential workers, bitterly opposed to Hitler, and wholly on our side, against whom there is no reproach or suspicion. If the most urgent task is that of utilizing the specialist services as fully and quickly as possible, the traditions of Great Britain, and it may well be its ultimate security, will not permit us to rest content with any policy which does not avail itself to the maximum extent of the good will and services at our disposal.

The utilization of the willing services, which we ourselves urgently need, and which are only too anxious to be enrolled, means far more than the mere material accession to our war effort implied. Failure to evolve the necessary safeguards demanded would augur ill for our capacity to embark on the much larger task of establishing a new world order after the war. Integration of such services, skill and knowledge into our effort, on the other hand, will testify to a freedom from hysteria, a capacity for competent organization, and to a loyalty to the ideals and traditions of humanity worthy of the cause for which we contend.

ANIMAL COLORATION AND NATURAL SELECTION

Adaptive Coloration in Animals
By Dr. Hugh B. Cott. Pp. xxxii + 508 + 49 plates. (London: Methuen and Co., Ltd., 1940.) 40*s*. net.

THIS excellent work, eagerly awaited for many years, will be most welcome to naturalists, even, we may hope, to the few who have hitherto rejected the Darwinian interpretation which the author has here supported by a mass of additional evidence based on his own observations and those of very many others. Dr. Julian Huxley, in his introduction, refers to one of these critics, the American zoologist, A. F. Shull, who writes in contemptuous terms of the whole subject. To this Huxley replies: "Dr. Cott, in this important book, has turned the tables with a vengeance on objectors of this type. He has shown that it is they who are the armchair critics, or, one might say, the laboratory-bench critics. Had they taken the trouble to acquaint themselves with even a fraction of the relevant facts to be found in nature, they could never have ventured to enunciate such sweeping criticisms".

"Adaptive Coloration", following the author's preface, is divided into three parts: (1) concealment; (2) advertisement; (3) disguise, including mimicry (in cuckoos as well as insects and the relations between the two forms of resemblance); finally, a brief conclusion in which the cumulative effect of the facts and arguments is shown to "present a body of evidence which makes it appear that adaptive coloration is one of the chief attributes of the higher animals, and has been, indeed, one of the main achievements of organic evolution" (p. 427).

The immense amount of labour devoted to the production of this great work may be inferred from the 685 titles of original memoirs quoted in the bibliography (pp. 439–66). A brief inspection of the list will at once show how much we owe to the author for bringing together and discussing these scattered records of observations on adaptive coloration in animals and for their certain result, the stimulation of further researches along the same lines as well as others which are sure to be developed as the work proceeds. Special mention must be made of the illustrations. The coloured frontispiece, by the author, exhibits the warning coloration of eight Amphibia, while forty-eight monotone plates, chiefly reproduced from his admirable photographs of living species at rest in their natural surroundings, and eighty-four text illustrations, supply the help which is so absolutely necessary in this subject. Prof. Hale Carpenter, in a recent review, has referred to "the scattering of the plates at random through the pages" and the inconvenience of the references to some of them. I, too, felt something of a shock, in reading the extremely interesting pages on crabs and the stinging sea anemones, their welcome and invaluable guests, to be suddenly faced by the lovely plate 30 (opposite p. 236), displaying an East African hawk-moth at rest on a tree trunk at Beira. There can be no doubt that a second edition will soon be required, and we may hope that the arrangement of plates and the references to them will then be improved.

In the limited space available it is impossible to treat adequately the first and much the longest of the three sections into which the book is divided, namely, concealment. I must, however, direct special attention to the admirable and abundant plates and text figures and the excellent account of the whole subject and each of the ten heads into which it is divided, as clearly shown in the table of contents.

On the subject of Part 2, advertisement—aposematic or warning colours—I believe that every open-minded reader of pages 191–233, devoted, with the accompanying plates and figures, to the methods by which different animals are rendered conspicuous in Nature, will agree with the author's statement that the classes of evidence "all point to the conclusion that *aposematic appearances are adaptive*: that they tend to satisfy a vital need in the struggle for life, *the need for recognition by predatory enemies as something unwholesome, something unwelcome, and something to be avoided*" (p. 233).

The succeeding section, on adventitious warning coloration (pp. 234–44), describes many examples of "relatively defenceless and palatable animals . . . known habitually to associate themselves with others which are specially protected and conspicuous, and thus to share the protection from enemies which the latter enjoy" (p. 234). Instances of such partnership between crustaceans and sea-anemones or other unpalatable forms were recorded long ago—an interesting British example by P. H. Gosse in June 1859 and several observed by Walter Garstang at Plymouth, a few years later. Extremely interesting and remarkable as these and other early records certainly are, I do not remember meeting with any criticism or doubt of an interpretation based on adaptation which was, I believe, offered by every observer. But the facts and their interpretation are so significant, and indeed arresting, that the admirable section in which the subject is brought up to date gave me special satisfaction and I hope it will be widely read, especially by those who are inclined to be critical of natural selection. A few of the many examples quoted by the author may be mentioned :

"The coral-haunting crab *Melia tessellata*, from Mauritius, invariably grasps two anemones, one in each claw—employing them both for defence and for feeding. Borradaile states that if the crab is assailed it thrusts the polyps towards the enemy and thus wards him off with their stinging tentacles, but if the polyps capture food, the crab takes the morsel from their grasp with one of its legs and transfers it to its own mouth" (p. 235). Other examples quoted are the damsel-fishes (Pomacentridæ) of the Indo-Australian Islands, which find protection among the stinging tentacles of certain large anemones and apart from these are unable to withstand the attacks of more active fishes (pp. 237–38).

Immediately following the account of associations observed in the life of the sea is a description of the nesting partnerships between birds and aggressive Hymenopterous insects, such as wasps, which Dr. J. G. Myers has carefully studied in South America and the West Indies (pp. 238–39). Dr. Cott concludes that the evidence as a whole "indicates that we have in these forest-dwellers a highly perfect and singular instinct correlated with the need for protection from enemies" and that it has its parallel "in the waters of coral reefs, where stinging anemones, rather than stinging aculeates, play the role of protector to the defenceless creatures who solicit their company" (pp. 239–40).

Dr. Cott has lightened and brightened his book by numerous admirably chosen quotations introduced into the text or appearing as headings to sections. Thus, referring in the preface (p. xiii) to the function of camouflage in aerial warfare, he points out that "we have lagged far behind nature, and have much leeway to make up before we can approach the efficiency attained by different forms of wild life in the field. We should do well, therefore, to follow advice from the Book of Job : 'But ask now the beasts, and they shall teach thee ; and the fowls of the air, and they shall tell thee . . . and the fishes of the sea shall declare unto thee' ". Another attractive and appropriate quotation, from Milton, supplies the heading (p. 290) to Section 9 : "Evidence of selective feeding by vertebrate enemies in a state of nature", containing abundant proof that the diet of many insectivorous animals is determined by palatability rather than availability, as some critics have urged. In the quotation the Archangel Raphael speaks to Adam of the "various living creatures" of the earth and air, and asks him :

"Know'st thou not
Their language and their ways ? They also know,
And reason not contemptibly."

It has been a very great pleasure to read Dr. Cott's fine work, to remember that it has been produced in this, the country of Charles Darwin, and that many excellent observations made in happier times by our present enemies are here described. May such happiness soon return !

E. B. Poulton.

WATER AND ALL ITS PROPERTIES

Properties of Ordinary Water-Substance in all its Phases
Water-vapor, Water and all the Ices. Compiled by N. Ernest Dorsey. (American Chemical Society, Monograph Series No. 81.) Pp. xxiv+ 673. (New York : Reinhold Publishing Corporation ; London : Chapman and Hall, Ltd., 1940.) 90*s*. net.

In this very remarkable book, Dr. Dorsey presents a series of nearly three hundred tables on the principal physical properties of water. The book continues the work commenced when the author was an associate editor of the International Critical Tables, for which he worked indefatigably. It is based, in respect of data obtained before 1923, mainly on these Tables ; for more recent data, the literature has been exhaustively searched, much more than a thousand references being given, and good use has been made of other tables and monographs. The breadth of knowledge and the conscientiousness with which this enormous mass of data has been digested and put into perspective compel profound respect.

All the ordinary physical properties of water are of course fully tabulated, for ice, water, and steam. Thermodynamic properties are fully given, including the data for the synthesis of water from its elements and for its dissociation. There are full tables of the spectroscopic and other optical properties, also of the magnetic, magneto-optic, dielectric, and acoustic data. The results of the X-ray examination of ice and water are summarized and the sections on surface properties, as would be expected from the author's earlier contributions to the subject, are very good.

Much information that is not capable of quantitative tabulation is also given. There are excellent descriptions of the entrancing phenomena accompanying the formation of ice; indeed this book excels in its account of the various properties of ice, and of their importance in many directions, including meteorology and engineering. There are a few short sections dealing with miscellaneous topics, such as the preparation of dust-free water, and the composition of sea water. The term 'water-substance' means water as found on the earth, that is, having the usual isotopic ratio of about one part in 6,500 of deuterium oxide; but a good deal of information is included on sea water, in various places in the book. The solubility of gases in water, and the diffusion of gases through such solutions, are discussed; but wisely the solvent power of water for other substances is not treated.

This book is a monumental piece of industry, guided and inspired by learning and a breadth of interest far beyond that of most scientific authors. Naturally it is not a book to read through, though many parts of it are surprisingly readable. It should be on the shelves of every well-equipped library, where it will be consulted by workers in almost every branch of science. It provides, immediately, data of sufficient completeness and authority for all but very highly specialized work; and even those intending to pursue any special part of the subject farther than it is taken here will find this book an admirable and extremely well-balanced introduction.

N. K. Adam.

HISTORY OF THE POWER STATION INDUSTRY

The Early Days of the Power Station Industry
By R. H. Parsons. Pp. x + 218 + 24 plates. (Cambridge: At the University Press, 1940.) 15*s*. net.

THE author says in his preface that so rapid has been the growth of the industry and so profound the changes it has undergone, that few of its original features are now recognizable. He has done well to give an account of electricity supply as it was in the days when every enterprise was largely of a pioneering nature and its future could only be guessed at. This period closed near the end of last century. At that time the lines along which progress would take place were becoming evident.

The birth of the power station industry was foreshadowed by Faraday's discovery, in 1831, that electricity could be generated by mechanical means. The author points out that we may say that the development of the dynamo in its present form started in 1845, when Wheatstone and Cooke patented the use of electro-magnets in place of permanent magnets for the field. Machines were not made completely self-exciting before 1866, when the brothers C. and S. A. Varley, Dr. Werner Siemens and Sir Charles Wheatstone independently and practically simultaneously, discovered the principle of self-excitation. The production by Gramme, in 1870, of a dynamo with a ring-wound armature brought matters to a point when the industrial generation of electricity really became a practical question.

The first company to be formed for the exploitation of electric machinery was probably La Société Générale d'Electricité, of Paris. It was founded in 1853 to develop a machine designed by Prof. Mollet for the purpose of generating current for the electrolysis of water. The object was to produce hydrogen and oxygen for making limelight. The project was not successful, but the machine was modified by Prof. F. H. Holmes and used for experiments in connexion with electric light. On December 8, 1857, the light produced by his second machine was thrown over the sea from the South Foreland Lighthouse.

Sir Humphry Davy showed in 1808 to the Royal Institution that a brilliant light could be produced by allowing an electric current to form an arc between a pair of carbon points, the current being obtained from a battery of 2,000 zinc-copper cells. For illumination, arc-lighting was the only way of utilizing electricity. In August 1878 six Lontin lamps were employed to illuminate the Gaiety Theatre; this was the first building in London to be lighted electrically. It was installed by French engineers.

The discovery of incandescent lamps by Edison and Swan and their wise agreement to amalgamate their interests in October 1883, so as to avoid litigation, was a great advance. If we confine ourselves to undertakings that have a continuous existence to the present time, the honour of priority should be given to that of Brighton. The history of the Brighton undertaking can be traced back to December 1881, when Robert Hammond went to Brighton and staged an exhibition of the Brush arc-lighting system. The response was so good that the Hammond Co. gave a permanent supply of sixteen arc lamps in series carried on an experimental circuit for nearly two miles.

On looking through the book, one is struck by the versatility of many of the great pioneers of the mechanical and electrical power industries. Among others, we may mention Colonel Crompton, born in 1845, a world pioneer of D.C. dynamos directly coupled to high-speed Willans engines, and Sebastian Z. de Ferranti (1864–1930), who designed the high-voltage A.C. generating station at Deptford. He was the world pioneer of high-voltage transmission.

One of the greatest engineers was Charles A. Parsons, whose name is well known as the inventor of the steam turbine. The results of his efforts to provide the electrical industry with a better prime mover and dynamo, was the invention of the turbo-generator. The first machine of this type was constructed by him in 1884, and it now has an honoured resting place in the Science Museum at South Kensington. The fertility of Parsons as an inventor is shown by his list of British patents, which number more than three hundred. He founded several large engineering works. His invention of the steam turbine has made it possible for electricity to become almost a necessity of industrial and universal welfare, instead of a costly luxury.

This volume will be of great interest to every engineer. It contains a large number of excellent photographic reproductions of early power stations. the facts are well authenticated and the interest never flags.

A. RUSSELL.

THE DRIFT FROM THE LAND

Proceedings of the Fifth International Conference of Agricultural Economists, held at Macdonald College, Canada, 21 August to 28 August 1938.
Pp. xiv + 436. (London: Oxford University Press, 1939.) 17*s*. 6*d*. net.

A STEADY decline in the agricultural population of every industrialized country is one of the most characteristic features of the present stage of civilization. The grave social consequences, if the decline continues, have frequently been portrayed, and some of them have already been experienced—even in countries which, like the United States, still have larger rural populations than can be accommodated under the prevailing economic system; for the decline is not only in numbers, but also in the strength of the bonds which tie the cultivators to the land. The cultivators are not so deeply rooted in the soil as formerly, and at any time an economic blast may blow them away.

The problem of the drift from the land is engaging the attention of sociologists and economists throughout Europe and North America. The solutions proposed to stem the drift do not include the return of sociologists and economists to the agricultural labours of their forefathers, and the recent failure of schemes for settling equally unsuitable material in the form of industrial unemployed on the land is leading to the abandonment of large schemes of rural resettlement. It is proposed, instead, to check the rural exodus by alleviating the lot of the dwindling minority which still remains tied to the soil—by substituting economic persuasion for the grim struggle for existence that Nature imposes on those who must sustain her challenge and hold the land for the use of mankind. There is, however, nothing in history to show that alleviating conditions for the front-line defenders of civilization either strengthens the defence against, or weakens the attack of, the antagonist who is always waiting to re-occupy the soil. But it is felt that something must be done to encourage the defenders, and it is up to those in the rear to do it.

In one form or another this problem was present in the minds of most of the speakers at the Fifth International Conference of Agricultural Economists. The four main sessions of the Conference discussed the social implications of economic progress in present-day agriculture; land tenure and social control of the use of land; farm labour and social standards; and international trade in relation to agricultural development. A dominant note in the Proceedings is struck by a widespread realization that the economic and political impacts of civilization are causing mankind to lose contact with the soil. A very high standard was maintained throughout the discussions, and it would be invidious to select any of the seventy-odd contributions for particular mention.

Agriculture has lagged behind in the rapid economic development which industry has undergone in the last century. Industry is now a corporate affair whereas agriculture is still largely individual, and many of the economic strains to which agriculture is now subjected throughout the world may be traced to the inability of the individual to hold his own against the corporation. If this be so, the remedy would appear to lie in some form of co-operative agricultural organization, either voluntary or enforced by the State. Such organization has, indeed, already saved the farming community from complete economic ruin by industry in many countries, but in so far as the farmer abandons his individualism he loosens one of his most valuable contacts with the land—most valuable, that is, from the point of view of the society he supports. The farming community forms a biological link between the land and the otherwise detached industrialized societies living in sublime ignorance of the soil and of the latent power of Nature to eject them from it. As the link weakens, either by a bodily or a spiritual drift from the land, the delicately balanced superstructure of industrialized society begins to totter, and economists, sociologists and politicians bestir themselves to restore the equilibrium while there is still time.

We can observe them at work all around us to-day, the economists explaining the causes and seeking the cure for the small material reward the cultivator gets for his labours ; the sociologists lauding the rigorous life of the countryside ; the politicians currying the once neglected favours of the agricultural community. Earnestly they strive to distribute more equitably the burden of supporting civilization between the superstructure and the foundations. The farmer is to be assured a fair market and price for his produce ; housing, sanitation, education, conditions of work and of leisure are to be improved ; the rival attractions of the town are to be brought to the countryside ; the countryman is encouraged to multiply his kind. If these economic and social measures fail to stem the drift from the land, political pressure can be brought to bear—as in Germany, where the recent *Erbhofsrecht* restricts the right of the peasant to alienate his land or to disinherit his son.

Nevertheless, it is noteworthy that in several countries within the last twenty years a marked improvement in the conditions of agricultural labour and in the amenities of country life has been accompanied by an accelerated drift from the land. The drift has been as strong in Germany, where men have thought, written and acted against it, as it has been in Britain, where men have thought—and occasionally written—about it, or in the United States where, until a few years ago, the individual farmer was left defenceless against the economic holocaust of the agricultural depression of the nineteen-thirties. It seems as though the economic and social antidotes which have been applied to the country have been taken in still greater measure by the towns, and the attraction exerted by the latter has increased rather than diminished. That, at least, is an impression one receives from the Proceedings of this economic conference, which was more concerned with elucidating the intricacies of the problem than with the superhuman task of formulating a solution.

The solution—if any—has, indeed, little or no relation to economics. America has a greater rural population than the land can profitably employ ; but it is not suggested that her rural troubles—and especially her main trouble of erosion which aggravates all others—would be alleviated by a depletion of the rural population sufficient to give the remainder a satisfying share of the wealth of the soil. The trouble lies much deeper than economics. The farmer has no particular value to the community—except as a food producer, and machines can perform most food-producing functions equally well—unless he is tied by a spiritual bond to the land, a bond which is strengthened by making life not easier, but more difficult for him. The bond is the struggle with Nature for mastery over the land. When man's mastery over the land has been secured, as it has been in most countries of Western Europe, it is questionable whether any economic or social measures will suffice to prevent those who can from escaping from the slavery of the land, and enjoying some of the fruits of man's victory and the physical satisfaction of eating bread won in the sweat of another's face. Indeed, it is questionable whether in these circumstances an artificially maintained rural population has a social, or, under modern conditions of warfare, even a military value which is not possessed equally by an urban population. The love and understanding of the land characteristic of the cultivator while the issue of the struggle with Nature is still uncertain are liable to turn to indifference when men must be induced by what practically amounts to bribery to keep their roots in the soil. They probably will not stay on the land without inducement, but if they are induced to stay their chief value to the community at large is that they do not increase the congestion in the towns. Their social value as a stabilizing factor, and their biological or spiritual value as a link between civilization and the rest of Nature are largely lost.

The bond with Nature, once broken, can only be mended by losing ground already won and then attempting to recover it. It is improbable that any people which has fought and won its battle will willingly retreat in order to fight again. The peoples of Western Europe hold their lands securely against the forests they have supplanted, and only a few men are now needed to protect the strong defences that have been erected against wild Nature. The bodily drift from the land may be stemmed, but the spiritual drift will go on. There is no longer any biological restraint to bind the great majority of men to the soil, and economic remedies are no substitute for the harsh bond of biological necessity that is now lacking. The pain and travail, the wind and rain in the fields, which are the essence of Nature's bond, are not for the economists and sociologists nor—if they can be avoided—for anybody else.

In America, on the other hand, the recently vaunted conquest of Nature by technocracy has been shown to be unreal. Desolation and destruction of the land have forced a retreat which can only be reversed by a people deeply rooted in the soil. The present drift from the land must be stopped and a spiritual bond forged between man and Nature. But the bond will be forged not by lightening the hard lot of the farmer, nor by otherwise encouraging a shallow-rooting human cover on the land, but by an unremitting struggle against the natural forces of adversity that mankind has released upon itself. Those forces are of biological and physical origin, and can be overcome—and the enduring fertility of the soil assured—only by biological and physical effort. The economics of the struggle with, and of the victory over, Nature are of great practical importance, particularly in these critical times, but they are not fundamental to the ultimate issue.

G. V. JACKS.

STUDIES IN MICROBIOLOGY

A Textbook of Microbiology

By Prof. Kenneth L. Burdon. Second edition of "A Textbook of Bacteriology". Pp. xv + 638. (New York: The Macmillan Company, 1939.) 14*s*. net.

SO far from being a text-book on general microbiology, as the title seems to imply, more than half this book is devoted to the medical aspects of the subject, little space being assigned to fermentation, soil microbiology and nitrification, micro-organisms in industry, and the like.

In the earlier portion of the book, some 150 pages, the fundamentals of microbiology are dealt with at some length, and an excellent account is given of the general properties and classification of micro-organisms, with chapters on the Protozoa, fungi and moulds, spirochætes and viruses, and the true bacteria. Part 2 is devoted to the laboratory study of micro-organisms—the microscope, culture media and culture methods, and isolation, with a section on disinfection. Under viruses and filterable micro-organisms, no explanation is given of the reason for their invisibility microscopically.

The remainder of the book gives an account of the relation of micro-organisms to disease, commencing with the sources and prevention of infection and aseptic technique. Chapters follow on resistance and immunity, anaphylaxis, and the practical use of vaccines and serums. Lastly, the microbiology of the chief infective diseases is considered. The treatment here is on somewhat novel lines, for the individual diseases are dealt with from the point of view of the regions of the body principally affected, the natural microbial flora of the region and the pathological conditions affecting the part being first considered, after which the micro-organisms responsible for these conditions, or likely to be present, are described.

The descriptions given throughout are clear and accurate and well up to date, and the treatment of the subject takes a middle course between an elementary text-book and an advanced treatise. We gather that the book has been designed as a general college course on the subject, rather than for the student of medicine and hygiene, and while serving as a useful outline for the medical student, it is scarcely full enough in many sections to be his only guide. As in many American textbooks, review questions are appended to the various chapters, and the book concludes with appendixes on bibliography, formulæ, and suggested laboratory exercises.

The book is very readable and free from mistakes, is well produced and illustrated, and some portraits of pioneers of the subject add to its attractiveness.

R. T. HEWLETT.

The Physics of the Divining Rod

Being an Account of an Experimental Investigation of Water and Mineral Divining. By J. Cecil Maby and T. Bedford Franklin. Pp. xv+452+6 plates. (London: G. Bell and Sons, Ltd., 1939.) 21*s*. net.

THIS is a very ambitious book: its aim is to provide a much-needed physical explanation of dowsing and to improve its technique on scientific lines and, at the same time, to present a coherent mathematical theory. The greater part of the book is written by the first author and surveys the whole field of former investigations, describing many others made by himself and his co-workers. In his survey Mr. Maby shows a very uncritical acceptance of a number of claims either very insecurely established or already discredited. This has an unfortunate effect on the scientific reviewer, and his confidence is not increased by finding that there is not a graph containing points which indicate actual observations: all are smoothed means and consequently their value cannot be assessed. Measurements with Wynn-Williams ionization counters are described but not in sufficient detail to make critical comment possible. Atmospheric ionization is not an easy subject experimentally.

The theoretical section, by the second author, postulates some form of cosmic radiation resulting in electromagnetic waves of ten metres wave-length. There seems to be no direct evidence for such waves, and the author's discussion of their polarization cannot be justified on our present physical knowledge.

In presenting facts and theories to the scientific world, there is a well-accepted and necessary procedure. It is to be regretted that the authors have not followed this procedure, thus making the position of the scientific reviewer impossible.

Fossil Orthoptera Ensifera

By Frederick Eberhard Zeuner. Text. Pp. xiii+321. 15*s*. Plates. Pp. iv+80. 20*s*. (London: British Museum (Natural History), 1939.)

DR. ZEUNER has written a monograph which transcends the immediate purpose of a British Museum catalogue. He has made a study of fossil Orthoptera and allied insects side by side with the recent species and, in this way, he has enabled the reconstruction with reasonable probability of the evolution of the group Ensifera. This latter assemblage includes the Tettigoniidæ, or long-horned grasshoppers, the Gryllidæ, or crickets, together with various allied families. It is shown that the Ensifera may be traced back into Upper Carboniferous rocks. Their ancestors were Protorthoptera and are closely related to those of the Acridian group or short-horned grasshoppers.

Dr. Zeuner is an expert at his task and, unlike some insect palæontologists, he has the knowledge necessary to combine the evidence derived from recent and fossil forms to good purpose. Passing over the purely technical descriptions of genera and species, the premises upon which the main conclusions are based form interesting and instructive reading. The author's accounts of the venation and of the sound-receptor organs, for example, have involved a large amount of independent investigation the results of which aid in solving the phylogeny of the insects concerned. We hope that the British Museum (Natural History) will see its way in future to publish more monographs, of larger or smaller groups, involving, like the present work, conclusions of fundamental importance to our understanding of their origins and affinities.

Buschi

Vom Orang-Säugling zum Backenwülster. Von Prof. Dr. G. Brandes. Pp. v+135. (Leipzig: Quelle und Meyer, 1939.) 4.80 gold marks.

"BUSCHI" is a somewhat discursive account of the growth of a celebrated male orang-utan belonging to the Dresden Zoological Gardens, to which it went when an infant a few weeks old, and where it is apparently still living, a mature and powerful ape enjoying, judging by its photographs, even less in the way of good looks than is normally possessed by orangs. Records are given of the animal's increasing weight, of the times of eruption of its teeth, of its sexual maturation, and its development of secondary sexual characters; much of this information is of considerable interest to students of human evolution. Dr. Brandes has also gone to great trouble in acquainting himself with, and in illustrating, the individual characteristics of other captive orangs, and his observations on the great variability of this species of ape are not without interest in relation to the general question of racial differentiation, and in particular with the more specific question of the existence or non-existence of races among orangs. The book is lavishly illustrated, but it has no bibliography.

Monograph of the South American Weevils of the Genus Conotrachelus

By Karl Fiedler. Pp. iv+365. (London: British Museum (Natural History), 1940.) 15*s*.

THIS work, the text of which is written in German, deals with a single genus of weevils that is extremely numerous in species. It is entirely devoted to descriptions of the South American members and the majority of these refer to new species. The genus includes a number of forms that are pests of cacao, custard apple, guava, together with certain Leguminosae and such fruits as plums, apricots, etc. The monograph is illustrated by one plate and various text figures.

Statistical Method from the Viewpoint of Quality Control

By Dr. Walter A. Shewhart, with the editorial assistance of Dr. W. Edwards Deming. Pp. x+156. (Washington, D.C.: Graduate School, Department of Agriculture, 1939.)

FOR many years Dr. Shewhart has concerned himself with the development of statistical methods in the practical business of quality control in mass production. This latest publication covers old ground and provides a didactic foundation rather than any new extensions of his previous ideas. R. A. F.

CO-OPERATIVE AGRICULTURAL RESEARCH IN THE AMERICAS*

By the Hon. Henry A. Wallace,
United States Secretary of Agriculture

THE Governments of the American countries look to men of science, on one hand, for sound appraisals of their hemisphere resources and, on the other, for scientifically sound judgments as to the methods under which these resources can best be utilized in order to promote the general welfare and raise the standard of living of all American peoples.

In this connexion, special emphasis must be placed on agriculture for a number of reasons. One is that agriculture plays a very vital part in the economies of all the countries of the Western Hemisphere, especially those of Latin America. Another is that at present these countries produce much the same types of agricultural commodities. A third reason lies in the fact that export trade is vital to the welfare of these countries, and it so happens that agricultural items represent very significant portions of either the export or the import trade of each of them.

As things stand to-day, the lines of production in the Americas and the nature of the merchandise exchanged between the republics present definite handicaps to a substantial trade expansion. This emphasizes the need of exploring the possibilities for greater agricultural production in Latin America of tropical or semi-tropical products that the United States needs and can readily import in substantial quantities. Developing agricultural production along these lines would provide a sound basis for complementary trade relations and place the trade between the two areas on a solid foundation. As a consequence, it would increase the buying power of Latin American countries for the wide variety of products that they want from the United States but which, in present circumstances, they are unable to buy here. Finally, the development and expansion of production of complementary, non-competitive products would furnish the spearhead of co-operative efforts designed to give practical significance to the idea of Pan-American solidarity.

The tropical and semi-tropical products include such articles as rubber, cinchona, abaca, kapok, rotenone, and other insecticides, tea, cocoa, camphor, and tropical hardwoods. Hundreds of millions of dollars are spent by the United States each year for such commodities as these, imported for the most part from distant areas outside of the Western Hemisphere. Experiments and investigations already undertaken by private concerns and under co-operative arrangements of American Governments have revealed some encouraging possibilities by way of developing profitable production in tropical areas of Latin America. Recently the United States have co-operated in four important agricultural surveys in Haiti, Paraguay, Ecuador, and Colombia at the request of their Governments. Members of the United States Department of Agriculture who made the surveys gained a knowledge both of the problems and possibilities in Western Hemisphere agriculture. Their experience should be most helpful in work on the specific projects that must be undertaken in the future.

In this connexion, it has been found that some limited facilities exist in the Americas for research in tropical agriculture. But, for a long-term programme that would call for continuing research designed, on one hand, to develop and promote tropical agriculture on a scientific basis, and on the other hand, to train the agricultural leaders of the future in this field, more adequate facilities than now exist are indispensable. For such a purpose some thought has been given to the possibility of establishing an institute of tropical agriculture in some Latin American country where facilities for tropical research are suitable.

It is our sincere belief that the establishment of an institute of tropical agriculture is vital if Western Hemisphere agriculture is to develop as it should. This proposal, which we in the Department of Agriculture have been considering for a couple of years, has been endorsed by President Roosevelt's Interdepartmental Committee on Co-operation with the American Republics. The Institute would serve as a symbol of amity and of the economic and cultural relations between the Americas. It would lead to a better balanced agricultural economy in the Western Hemisphere. It would be in a position to present comprehensive data on the vital agricultural problems of all the American republics. It would develop a broad knowledge of pests and diseases common to the great tropical region. In bringing together students in agricultural science, it would promote a mutual understanding between these future leaders in agriculture. Through co-operative research it would work towards the solution of serious problems in crop and animal production such as the Sigatoka disease of banana, witch broom and Monilia rot of cacao, and animal parasites.

---

* Substance of a paper prepared for delivery at the session devoted to agriculture and conservation, Eighth American Scientific Congress, on May 11.

The Institute would not only provide technical training but also an opportunity to acquire a knowledge of the languages and the varied business methods, standards of ethics, and points of view of the Western Hemisphere.

Research on rubber production should meet with the approval of all those interested in or responsible for Western Hemisphere policies. Rubber is the most important of all tropical agricultural products. Although indigenous to South America, rubber is not grown there commercially to any extent. Indications are, however, that it could be and should be an important product of this hemisphere. The Goodyear Company, with its plantings in Costa Rica and Panama, and the Ford Company, with its plantings in the Amazon region of Brazil, have been pioneers in the plantation-production of rubber here. Research should be undertaken on modern production methods, such as soil management and the developing of high-yielding disease- and insect-resistant strains which can be used in bud-grafting. Such research would doubtless lead to the economical production of rubber.

It is our feeling that an institute of tropical agriculture cannot be established unless, in the beginning at least, the bulk of the necessary funds are subscribed by private foundations or individuals. Governments of the American Republics could participate directly by sending students to study in the Institute, assigning problems to the Institute for solution and perhaps furnishing part of the faculty. The problems assigned to the Institute would be of a kind that Governments would find it cheaper to pass on to the Institute for solution. The Institute, of course, would be equipped to work on large and important agricultural problems, at less cost and with greater certainty of solution than elsewhere.

Discussions of the Institute always bring up the question of location. It is our feeling that it should be located in a Latin American Republic under good environmental living conditions ; but, at the same time, be so situated as to be easily accessible to places having conditions favourable for the development of tropical crops like rubber, abaca and vegetable oils. Some Governments have indicated a desire to have such an institute in their countries, and a willingness to furnish sites for its location.

The fusing of agriculture and conservation in this section of the Eighth American Scientific Congress is entirely logical. If, in its truest sense, agriculture means the science and art of wresting vital human needs from the soil and the resources dependent upon it, it is essential that we should think simultaneously of conservation. Agriculture and conservation must progress hand in hand. The former could not long exist without the latter. The Americas have resources yet untapped.

Having gone through a long period of exploitation, coincident with settlement of the continent, we in the United States are now striving to reverse the trend and move as rapidly as we can toward the conservation of our resources in order to ensure sustained use. Conservation of natural resources is the pronounced policy of our Congress, and the executive branches of Government, in co-operation with individuals, co-operative groups, and corporations, are carrying on constructive programmes in this direction.

In undertaking to protect our natural resources for permanently sustained use, however, we promptly discovered several formidable gaps in our knowledge. We were aware, for example, that soil erosion was wasting our soil and its fertility at an incredibly rapid rate. But we had no precise knowledge of the extent of erosion in our country, and we had no extensive knowledge of the varying rates of erosion on different types of soil and under varying kinds of ground cover.

In recent years we have devoted an increasing amount of time and energy to gathering basic facts about our agricultural plants. This kind of inventory, in my opinion, is indispensable to the intelligent. conduct of agricultural programmes. How can we hope to conserve our resources for the continuous use and maximum long-time benefit of our citizens unless we know what resources we have, as well as their quality and quantity ?

In 1934, we made a reconnaissance to find out just how extensive and severe erosion of the soil had become in the United States. We learned that much of the land of the United States had been damaged to some extent and that not a single State had escaped. We learned that great areas had been ruined or severely impoverished. We learned where erosion is most severe, the types of erosion that had caused the most damage, and got some idea of the relative effectiveness of our major crops in protecting the soil or exposing it to the elements.

In the Americas, I believe, we have an obligation to ourselves and to the world. It is to develop our resources for the maximum benefit of mankind, yet, while developing them, to ensure to posterity their prolonged usefulness. Depending on our choice, we can exploit our resources, exhausting them completely, or we can draw steadily on them as requirements demand, preserving the source for future generations.

STRUCTURE AND COMPOSITION OF PLANT CELL MEMBRANES

BY WANDA K. FARR,
DIRECTOR, CELLULOSE LABORATORY, BOYCE THOMPSON INSTITUTE FOR PLANT RESEARCH,
YONKERS, NEW YORK

HISTORICAL CONCEPTION OF MEMBRANE COMPOSITION

THE complex structure and chemical composition of plant cell membranes were indicated in the reports of the earliest study of cells as biological units. Before 1850 the work of Payen[1] had shown that different proportions of carbon, hydrogen, and oxygen were obtained from some of the separable membrane constituents. During succeeding years, considerable progress was made in correlating chemical analyses with observed microscopic structural features of various types of membranes.

The observations of these early botanists and chemists were carefully reviewed by Mangin[2] in his memoirs on the pectic compounds published in 1891–92. A constituent, almost universally present in plant cell membranes, which was very resistant to ordinary chemical and physical treatment, they had named 'cellulose'. From the point of view of orderly molecular arrangement, as indicated through observations in polarized light, this material was seen to be fundamentally crystalline and, in many cell membranes, in the form of diminutive fibrils varying in length and arrangement. In intimate association with the cellulose they found other substances of carbohydrate nature which definitely fell into the colloidal group in Graham's classification of chemical substances. To this group of carbohydrates as a whole they gave the name 'pectic substance'. Mangin concluded that pectic substance exists in cell walls along with cellulose from the earliest stages of formation of the membrane. He also suggested that various phenomena associated with cell wall modification, such as gelatinization and liquefaction, are due to the transformation of pectic materials.

MODERN CONCEPTIONS OF MEMBRANE COMPOSITION

This earlier work, indicating a heterogeneous composition of the plant cell wall, including the cotton fibre, has been generally disregarded during more recent years by leading workers in the field of cellulose chemistry. Instead, attempts have been made to explain reactions of the cotton fibre by analogy with the behaviour of pure substances the molecules of which are in the form of long chains. The conclusion has been drawn that variations in viscosity produced by the fibre mass can be accounted for upon the basis of variations in the degree of polymerization of the cellulose molecules. The behaviour of dispersions of derivatives of cellulosic materials has been interpreted in a similar manner. The direct application of this concept, even to the behaviour of purified cotton fibres, assumes chemical homogeneity in the fibre mass.

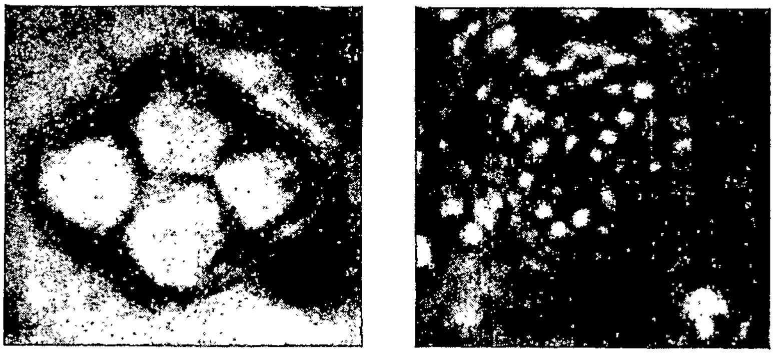
Along with this growing tendency to interpret the behaviour of the cotton fibre membrane in terms of a single organic chemical, data concerning individual fibre reactions which are incompatible with this conception have continued to accumulate. A membrane which can be shown to contain as much as 90 per cent cellulose in the form of spirally arranged fibrils, exhibits colloidal behaviour of various types not in keeping with the known chemical stability of this substance. Many of these reactions, if carefully controlled, are reversible, leaving the fibre apparently unchanged. While the techniques of microscopy and X-ray diffraction have established the fundamental crystalline nature of cellulose, the single fibre and the fibre mass in many types of reagents behave as a colloidal system. These various types of information have served to increase the uncertainty concerning the physical structure of cell membranes and the chemical nature of the membrane constituents.

CURRENT OBSERVATIONS OF MEMBRANE COMPOSITION

In 1934, after a five-year period of study by means of microscopy, X-ray diffraction, and chemical analyses, the universal presence in cell membranes from all parts of the plant kingdom of a uniform-sized cellulose crystallite was established[3]. This paved the way for a clearer understanding of the variable reactions which had been observed in cell walls. These crystallites are remarkably stable physically, and although diminutive in size ($1{\cdot}5\mu \times 1{\cdot}1\mu$), lend themselves to separation from the other membrane constituents and to both optical and microchemical analyses. They are definitely doubly refractive in polarized light; the refractive indexes of dry particles from the cytoplasm of a living cotton fibre are 1·565 lengthwise and 1·530 crosswise; they react in a manner characteristic of cellulose in the presence of sulphuric acid and iodine; and their elementary analysis is:

	Theoretical value	Found
Carbon, per cent	44·4	44·34; 44·30
Hydrogen, per cent	6·17	6·31; 6·29 (no ash)

Their X-ray diffraction pattern is that of native cellulose, and when treated with 18 per cent sodium hydroxide they give the pattern of mercerized cellulose. In other words, these ellipsoidal particles show the characteristic properties of cellulose and were designated by us 'cellulose particles'.



(A) (B)

(A) STARCH GRAINS IN THE PROCESS OF FORMATION IN A PLASTID FROM THE LIVING PROTOPLASM OF A COTTON LEAF CELL. (× 2500).

(B) CELLULOSE PARTICLES IN THE PROCESS OF FORMATION IN A PLASTID FROM THE LIVING PROTOPLASM OF A COTTON FIBRE. IN THE GROWING PLASTID RINGS OF EQUAL THICKNESS AND VARYING DIAMETER ARE FORMED SUCCESSIVELY AT THE INTERFACE OF THE PLASTID PLASMA AND THE PLASTID MEMBRANE. THESE RINGS FRAGMENT DIRECTLY TO FORM THE UNIFORM-SIZED CELLULOSE PARTICLES SHOWN IN THE INTERIOR OF THE PLASTID. (× 1500).

During the period of wall formation, the cellulose particles appear in the outer regions of the cytoplasm arranged end-to-end in orderly single rows. The fibrils thus formed can be removed from the living cells for more careful study. It then becomes clear that each particle in the fibril is coated with a viscous substance which functions as a cementing material, holding the particles together to form the fibril, and the fibrils, layer upon layer, to form the membrane lamellæ. The heterogeneous composition of the membrane is therefore clearly visible in the form of a system having a continuous colloidal phase and a discontinuous crystalline phase. The crystalline phase is made up of the cellulose particles in various forms of orientation in the different types of membranes. The colloidal phase is chemically complex in any membrane and varies widely in chemical make-up as well as relative proportion to the crystalline phase in different types of membranes.

Membranes of moist cotton fibres from the unopened boll can be disintegrated into fibrils and particles by mechanical treatment alone. The membranes of mature, dried fibres require controlled treatment with chemical reagents to bring about a similar degree of membrane disintegration[4]. As the reaction proceeds, the material surrounding the particles is observed microscopically to swell and, in so doing, to push the particles farther apart. Long-continued treatment brings about the removal of the cementing material. The significant fact is that complete membrane disintegration is thus brought about without indication of change in the physical state of the cellulose particle. The characteristics of the colloidal substances which are removed in the process of this disintegration are, in general, those described by botanists of the last century as pectic substances. It is not implied that all of these constituents of the membrane will meet the requirements of the modern chemical concept of pectic material. In our own laboratories, in addition to pectic acid[5] we have two separable constituents of the inter-particle phase not yet fully identified. There are probably more fractions than these, even in a cementing substance so comparatively simple as that of the cotton fibre. In lignified and suberized membranes many new constituents in this phase of the membrane make the problem increasingly complex.

Microscopic analyses show that the cellulose particles in the membrane of the cotton fibre are not completely freed from all traces of the cementing material until after complete fibre and fibril disintegration has taken place. These observations indicate the possibility that an intimate physical, rather than a chemical, union between the diminutive crystallites and the thin surface coating of colloidal material may more nearly explain the observed properties of the membrane. In the final analysis both types of bondage may be found to be in operation. In any event, a satisfactory interpretation of the behaviour of the cotton fibre must take into consideration all the components which go to make up its intricate fibrillar and lamellate structure. Standard purification treatments frequently show little measurable effect upon the more general physical properties of the fibre.

Techniques are not yet available that will indicate finally which, if any, of the fractions of the cementing material can be removed without producing complete disintegration of the membrane.

The heterogeneous chemical nature of these plant cell membranes is not clearly in evidence in many of the experimental procedures now in common laboratory usage. Under the specific conditions employed, the conception of chemical homogeneity is frequently adequate for the final interpretation of data. The discovery of the cellulose particle, the observation of its intimate association with the cementing material, and the reactions of this two-phase system in different types of reagents do not conflict with the results obtained by other workers who have studied the reactions of plant cell membranes, assuming them to be pure cellulose[6]. Rather they represent a more detailed consideration of many of the experimental techniques now commonly used. The uniform shape and diminutive size of the cellulose particles, along with their even distribution in the colloidal material, tend to produce those reactions of the membrane long observed by workers who considered it a single-phase rather than the two-phase system which we have found it to be.

In the course of these first observations of the formation and structure of plant cell membranes, by cellulose particles and cementing material elaborated in the protoplasm of living plant cells, no clue was obtained as to the mechanism of formation of the cellulose particles themselves. During the past few months living cells of tropical marine algæ have proved to be excellent material for the solution of this problem. As the plastid enlarges, upon the inner surface of the chloroplast membrane are formed successively rings of varying diameter but equal thickness. These rings fragment directly to produce the uniform-sized cellulose particles.

In the cotton fibre and many other types of higher plant cells, colourless plastids produce cellulose particles by essentially the same mechanism. In chlorophyll-containing cells of the higher plants, the sugar and starch are manufactured in the chloroplasts and the cellulose in separate colourless plastids within the same cell. Starch formation in plastids of living cells was described before 1850. Cellulose formation has been more elusive and the mechanism which we now find in operation in many types of cells has been hitherto undescribed.

COLOUR VISION AND CHROMATICITY SCALES

By Dr. W. D. Wright,

Imperial College of Science and Technology, London

Colour Vision

It is no easy matter to assess the value of recent additions to our knowledge about colour and colour vision. So much fundamental information had been recorded twenty-five or fifty years ago by König, Abney, Helmholtz, v. Kries, Hering and other pioneers, that modern work appears at first sight to consist largely of filling in gaps here and there, and of improving the accuracy of the data by taking advantage of improved apparatus and photometric technique. This is especially true in regard to colour mixture and colour discrimination data, while on such questions as colour contrast, after-images, colour fatigue and the like, an enormous amount of quantitative work still remains to be done.

One most important feature of modern research, however, is that there exists a marked disinclination to make extensive theoretical deductions that have no adequate experimental backing. Earlier, highly ingenious and involved theories of colour vision were developed on the flimsiest of foundations, and burning controversies would be waged as to their relative merits; all this, in spite of the fact that very little was known about even the first reaction that takes place when light enters the cones, the colour perception mechanism in the retina. Perhaps only subconsciously, but none the less definitely, it has at last become recognized that the assault on the mysteries of the retina and brain is not going to be carried by a *Blitzkrieg*, either theoretical or experimental; there can be no short-circuiting of an immense amount of patient and laborious investigation.

Nevertheless, there has been progress. On the purely physiological side, a great deal of very valuable information has been accumulated about visual purple and its derivatives. This is, in a sense, only a preliminary to an examination of the colour perception mechanism, since visual purple is essentially associated with the rods, and the marked difference between rod vision and cone vision suggests that any photochemical substance occurring in the cones is likely to be very different from that in the rods. Further, with the aid of modern amplifier equipment, physiologists can now record the electrical impulses sent out along a nerve fibre from a single receptor in the retina of an excised eye, following stimulation by light. Investigations have already been started to measure the variation in the response with wave-length, and in the near future we may hope to learn whether or no three types of receptor sensitive to different parts of the spectrum do exist. This may perhaps be the most important single step forward since visual purple was isolated.

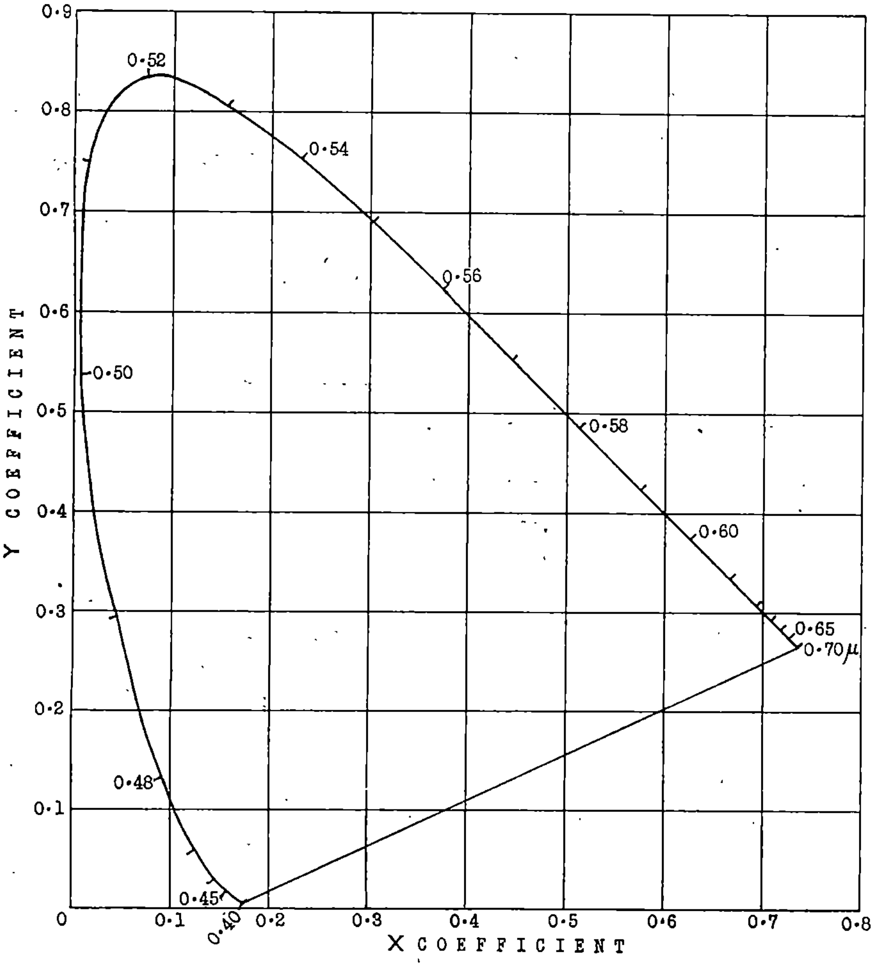

Fig. 1.

THE C.I.E. COLOUR CHART PLOTTED WITH RECTANGULAR CO-ORDINATES, SHOWING THE LOCUS OF THE COLOURS IN THE SPECTRUM.

Subjective investigations have also, during the past few years, broken fresh ground. The data about the different types of colour-defective observer are now very much more complete, especially as regards luminosity, colour mixture and colour discrimination. Again, very remarkable effects have been observed by varying the angle of incidence at which a narrow pencil of light strikes the retina, and they have led to suggestive ideas regarding the operation of the light-sensitive layer in the retina. A third type of investigation is that in which adaptation changes have been recorded quantitatively by a method of binocular matching, in which one eye is kept in a constant state of adaptation and used as a reference against which changes induced in the other eye can be recorded. By this means, photochemical and electrical reactions that would be most difficult to record by any direct physiological method can be followed with comparative ease.

In spite of this steadily increasing volume of information, it is doubtful whether workers on colour vision would be prepared at the moment to say more than that there is a photochemical reaction in the cone, and that at some stage, almost certainly in the retina, the response divides into three components. How this division occurs, how the three types of response that we may for convenience label red, green and blue, are transmitted separately to the brain, and how they are identified when they arrive, are questions that cannot yet be answered.

COLOUR MEASUREMENT

Because colours can be matched by an additive mixture of three radiations (generally, but not necessarily, a red, green and blue are chosen), it is possible to specify a colour in terms of the amounts of the three radiations required to match it. For measurements to have a recognized meaning, a number of factors have to be standardized. Modern colorimetry dates from 1931, when the Commission Internationale de l'Éclairage (C.I.E.) standardized the colour mixture data of a 'normal' eye and introduced a standard framework in which any colour could be specified.

In the C.I.E. system a colour is expressed in terms of the three co-ordinates X, Y and Z by an equation of the type

$$C = x.X + y.Y + z.Z.$$

X may here be regarded as the red co-ordinate, Y as the green and Z as the blue. Since the colour is governed only by the relative proportions of the three components, no loss of generality in the colour specification is introduced if the coefficients

$$x + y + z = 1.$$

In this case the amount of colour represented by such a unit equation is known as '1 trichromatic unit' and since, with this restriction, there are now only two independent variables, any colour can be represented by its position on a two dimensional diagram. Thus the locus of the spectrum colours in terms of the C.I.E. co-ordinates is given by the curve in Fig. 1, and this diagram may be regarded as the C.I.E. colour chart, the distribution of colours in the chart being governed by the particular choice of the reference colours X, Y and Z and their units.

The stage was thus set for the development of a practical system of colorimetry, but although this standardization was a necessary preliminary to the actual business of making standard colour measurements, much remained to be done.

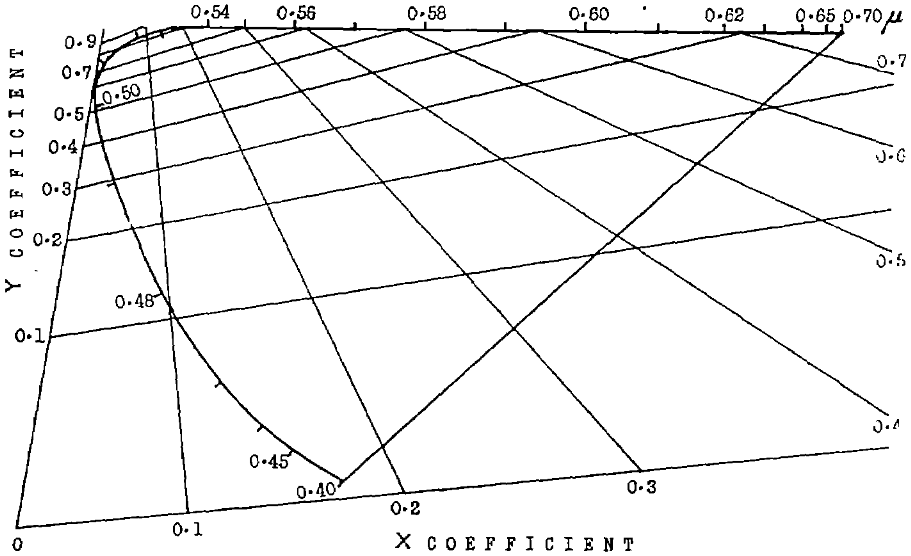

Fig. 2.

THE SPECTRUM LOCUS PLOTTED ON AN OBLIQUE PROJECTION OF THE C.I.E. COLOUR CHART TO GIVE A MORE UNIFORM COLOUR DISTRIBUTION.

The measurements can be made either visually or by means of a photo-electric device. In either case the accuracy of the measurement may have to be very high, because when two samples of considerable area are compared side by side the eye is extremely sensitive to quite small colour differences. In a visual colorimeter, the matching field has to be small owing to the structure of the eye, so that matches may not be possible to the accuracy demanded by the customer. Again, unless the matches are recorded by an eye that has the same characteristics as the standard eye, there will in general be a residual error from this cause. Difficulties of this kind can to a considerable extent be overcome by the extensive adoption of substitution methods. There is nothing illegitimate in doing this—substitution methods are continually in use in photometry—but it undoubtedly adds to the complexities of colorimetry.

It is not difficult to design a photo-electric colorimeter that has, in most cases, sufficient sensitivity, but it is very difficult indeed to produce an instrument that will give the right answer. For this purpose, three photo-cells are required that have spectral sensitivities corresponding to the X, Y, Z distribution curves through the spectrum, or linear transformations of these curves. This result might be obtained by one cell and three colour filters, or three cells and three filters, the filters being either normal gelatine or glass filters, or more probably spectrometer systems with a suitable template in the plane of the spectrum. A very considerable amount of development work still remains to be done before a satisfactory instrument on these lines is available for industrial purposes.

A more indirect approach is to measure the energy distribution through the spectrum of the light from the sample. When this is known, the calculation of the colour co-ordinates from the standard C.I.E. data is perfectly straightforward. This method, which only involves matches between two halves of a field of identical physical composition, has the outstanding merit that the spectral sensitivity of the eye or cell that is used has no effect on the result. It is, however, either very laborious or, if a recording spectro-photometer is used, very costly in equipment and operating personnel. It is a question for the industrialist to decide whether the cost is justified. The decision should, however, be made in the light of the fact that the spectrophotometric curve has other uses than just the calculation of the colour co-ordinates of any particular sample ; in the case of dyes, for example, it provides the essential data from which the colour of a mixture of dyes can be derived, and thus enters into the very heart of the dyeing industry. It is not to be expected that an elaborate device such as the photo-electric spectrophotometer will at first be able to compete economically with the experience of the craftsman acquired through many decades in industry, but there is no doubt whatever that here is a tool which should in time prove to be of the greatest possible value.

CHROMATICITY SCALES

It is of interest to consider whether, after a testing period of nine years, the system of colorimetry recommended in 1931 is free from criticism. Inevitably a few minor points have arisen that have called for further discussion, but it may be said that as a means of colour specification the system has proved entirely satisfactory and is being very widely adopted. It is from a somewhat different point of view that the system has proved less satisfactory. It has already been suggested that the diagram in Fig. 1 is not only a graphical means of expressing a numerical result, but also has to perform the additional functions of a colour chart. A good colour chart is characterized by a uniform grading of colours from one part of the chart to another, but in this the C.I.E. diagram fails, and fails in no small degree. What is required is a 'uniform chromaticity diagram', to use a term popular in the United States, in which a given distance always corresponds to an equivalent colour difference, in whatever part of the diagram and in whatever direction the distance is measured.

A uniform distribution of colours is not desirable for any pictorial virtues that it might possess, but for very material considerations of convenience when expressing colour tolerances and when estimating the importance of errors in matching, say, a number of dyed samples. An arbitrary re-distribution of the colours in the C.I.E. diagram is not possible because, on the trichromatic system, there is a definite algebraic relation between different points in the colour field. By certain linear transformations a new oblique projection of the present diagram could be used, and by this means a closer approximation to a uniform distribution can be obtained. At the moment further experimental data on colour discrimination are required before a final decision can be reached as to the projection that will give the most uniform distribution.

The disadvantages of using a fresh diagram are that either a new system of co-ordinates must be adopted, or else a specially prepared colour diagram must be used in which the X, Y and Z co-ordinates are no longer rectangular. Fig. 2 shows a diagram of this type due to Holmes[1], in which the colour field has been distorted to the shape required to give the uniform chromaticity scale proposed by Breckenridge and Schaub[2]. A change in the co-ordinate system itself is certainly to be deplored unless unavoidable ; not only would it cause a great deal of inconvenience, but also it would tend to discredit colorimetry in the eyes of the industrialist. If a diagram such as Fig. 2 is ultimately adopted, it will always have to be borne in mind that the uniformity of colour distribution is at best only approximate. Further observations will show whether the approximation is sufficiently good to be worth having.

OBITUARIES

Mr. H. Guthrie-Smith

THE death of Mr. H. Guthrie-Smith, fellow of the Royal Society of New Zealand, recorded in *The Times* on July 8, is a very sad loss. Not only was he one of the most observant and learned of Dominion naturalists, but also a man of great kindness and charm.

Tutira, his homestead, between Napier and Wairoa in the Hawke's Bay Province of New Zealand, has become a classic from his fascinating book, "Tutira—The Story of a New Zealand Sheep Station" (1920 ; second edition, 1926), which gives a full history of all the changes that have taken place day by day on the station during the past fifty or more years. In this account he gives a comprehensive picture of the physical features, soils, erosion and surface slips, the former forest covering and the vegetation which covered the area of the station before settlement. Then come interesting chapters dealing with the changes which have gradually or rapidly taken place due to chance or deliberate plant introductions and the stocking of the station with sheep, and later with cattle and goats, in order to check the insidious blackberry, which has brought such havoc on Tutira ; getting a hold during the War of 1914–18 when labour was scarce, it has spread like a devouring plague. In a letter to me a few years ago, after referring to the devastation of the rare native vegetation of the Kermadec Islands by goats which had recently been liberated there, he wrote:

"Reverting to goats where the blackberry is worst the cocksfoot grass holds best, its crown just sufficiently protected from the nibbling sheep—we have therefore the curious paradox of the more blackberry the better sward!"

Guthrie-Smith refers to the great increase of sparrows, starlings, blackbirds and thrushes, which all help to spread the blackberry, but points out that the goat, which certainly helps to keep it down, unfortunately eats everything else that comes in its way.

Guthrie-Smith had an intimate knowledge of the native New Zealand flora and of the introduced and naturalized plants, and his knowledge of the fauna was equally extensive, as readers of "Tutira" will well remember. His last book, "Sorrows and Joys of a New Zealand Naturalist" (1937), records his wanderings over many parts of the mainland and to the uninhabited islands, both to the north and south, to watch and study the birds. This, like "Tutira", is written in a very pleasant literary style, illuminated by the humour and imagination which made him so delightful a companion.

His earlier book on New Zealand birds, "Bird Life on Island and Shore" (1926), equally pleasantly written, contains vivid descriptions of species new to European readers. Other books were "Crispus a Drama" and "Mutton Birds and Other Birds".

Guthrie-Smith was born at Helensburgh in 1861, and was the son of Mr. John Guthrie-Smith of Mugdock Castle, Stirlingshire. Very soon after he left Rugby School, he went to New Zealand, where he acquired Tutira, some 20,000 acres, and made it his home. His carefully recorded observations of the changes which have taken place due to human interference, are of the greatest value, and he will be remembered with gratitude by scientific workers and naturalists both now and in years to come.

ARTHUR W. HILL.

Dr. Phyllis M. Tookey Kerridge

By the death, after a short illness, of Dr. Phyllis Margaret Tookey Kerridge, on June 22, the subject of physiology loses one of its ablest women workers, and several circles mourn a valued friend and colleague. The only daughter of Mr. William Alfred Tookey, of Bromley, Kent, she was educated at the City of London School for Girls, and at University College, London. Most of her post-graduate years were spent at the latter institution, first in the Department of Chemistry, in which subject she had taken an honours degree in 1922, and afterwards in the Department of Physiology, in which she was a lecturer at the time of her death. She also worked for various periods of time at the London School of Hygiene and Tropical Medicine, the Marine Biological Association Laboratory at Plymouth, the Carlsberg Laboratories at Copenhagen, and the Medical Unit of the London Hospital. While acting as a lecturer in the Department of Physiology at University College she studied medicine at University College Hospital, qualifying in 1933, and obtained the M.R.C.P. in 1937.

Dr. Kerridge contributed to the advance of science in several directions, covering a wide field. Her earliest work was in physical chemistry, from which she passed to the applications of that subject to problems of biology, her most distinguished work in that direction being the introduction and perfection of the glass electrode for the measurement of hydrogen ion concentrations of body fluids and tissues. This work won her an international reputation. After qualification in medicine she turned to the applications of physics, chemistry and physiology to practical requirements of medicine, and here again she distinguished herself, first in connexion with the perfection and investigation of the mode of action of the Bragg-Paul pulsator for the performance of artificial respiration, and secondly, in the many problems connected with the use of hearing aids for the deaf, and the study of the incidence of deafness in children. In this work her human sympathies found expression and her love of music gave it interest and value. For none of this clinical work, so greatly appreciated by the large number of deaf people whom she served so gladly, would she ever take a fee of any kind. The work was afterwards extended to embrace the study of speech in deaf-mutes, and had already achieved notable results. She also carried out, in collaboration with various colleagues, a number of researches of more academic interest—on buffering in tissues, on the conditions for albuminuria, and in several other directions.

All her investigations illustrated her wide acquaintance with methods, and a sure grasp of the experimental approach to a problem. As a teacher also, Dr. Kerridge will long be remembered by the many students who profited by contact with her fine and stimulating personality. Often she would encourage them to participate in her investigations, and to go round with her during their vacations on visits to Special Areas and slums in search for factors in the etiology of deafness in school-children.

Immediately on the outbreak of war, Dr. Kerridge joined the staff of an Emergency Service Hospital, where she and her colleagues fitted up an improvised laboratory for use in pathological and blood transfusion work. While this was in progress, and in the subsequent weeks and months, her cheerful personality and zeal did much to encourage all with whom she came into contact.

Dr. Kerridge was a keen musician, and a lover of the country and all that it brings to make life worthwhile, a capable botanist and ornithologist, and always a most cheerful, loyal and helpful colleague. The passing of so gallant a spirit will leave a gap in many places, and if the world of science is the poorer for her loss, it is the richer for the achievements she leaves behind after a relatively short, but very full, life. She was thirty-eight years of age.

C. LOVATT EVANS.

NEWS AND VIEWS

War Seventy Years Ago

Just seventy years ago the Franco-German War broke out. It is interesting in this connexion to quote extracts from a leading article entitled "War" published in Nature at the time:

"The dogs of war are again let loose, and in the two most highly civilised countries of Europe, where, a week ago, science, education, and commerce were in full sway, all the arts of peace are already neglected, and in prospect have gone back a quarter of a century. This journal, of course, has nothing to do with Politics: the function of Science is to unite the whole human family, whereas the function of Politics seems to be, both in the case of the human family and of each nation, to create parties and to emphasise them as much as possible, the object in each case being place for the partisans—whether that place be an income of a few thousands a year in one case or increased territory in the other. But although we cannot discuss politics, we may point out that as Science advances such policies will be overridden—that when Science and Education have taken their proper position—when the sword has given place to brain—when more of the best men of each nation take part in each nation's counsels, the dreadful thirst after blood will give way to something better; monarchs will see the folly of being surrounded merely with empty helmets and uniforms, or at all events if they do not, others will; and much will have been done when the pampering of armed men shall cease."

"If England is to prepare for war, the abnormal condition, so let it be; but surely, *a fortiori* she should *prepare for peace*, the normal one, as well. This has never struck her ministers, and the reason is not far to seek. But this is not all; the same disregard for science, arising from the ignorance of science among our rulers, has probably placed us in another position of disadvantage. While France and Prussia have been organising elaborate systems of scientific training for their armies, a recent Commission has destroyed what little chance there was of our officers being scientifically educated at all. As there is little doubt that a scientific training for the young officer means large capabilities for combination and administration when that officer comes to command, we must not be surprised if the organisation of our army, if it is to do its work with the minimum of science, will, at some future time, again break down as effectually as it did in the Crimea, or that our troops will find themselves over-matched should the time ever come when they will be matched with a foe who knows how to profit to the utmost from scientific aids."

"While, therefore, the Continent is being deluged with blood, let us *prepare for peace* as well as for war; let us prepare ourselves for victories in the arts, conquests over nature; let us, by means of a greater educational effort, more Science Schools, a truer idea of the mode in which a nation can really progress, fit ourselves to take our place among the nations when peace returns."

A Tax on Learning

While speaking in the debate on July 24 in the House of Commons on the Budget resolutions, Mr. A. P. Herbert took up the question of the proposed sales tax in its application to books, which have been placed in the category subject to 12½ per cent tax. It will be remembered that the subject was discussed at length in Nature of May 11, p. 719. As one of the representatives of the University of Oxford, and himself an author of distinction, it was wholly appropriate that Mr. Herbert should identify himself with the movement for treating books as a commodity apart and entitled to special consideration. As he pithily remarked, he was "not speaking so much of pennies as of principle. The taxes on knowledge were finally wiped out between 1850 and 1870, and the principle was established that we would not put a tax on things of the mind." For the sake of the £500,000 which it is estimated that the tax on book sales will produce, we are being committed "to do this barbarous thing".

Lord Wolmer replied to Mr. Herbert on behalf of the Government; he said that the whole purpose of the sales taxes was to curtail consumption, and that no case had been made for regarding books differently from other commodities. No one will wish to quarrel with the general views expressed by Lord Wolmer, but we still insist that books should be exempted from this impost. The general shortage of paper and other material must lead to a reduction in quantity of publications in any event, and, as Mr. Herbert pointed out, if one new thought is held back from publication by the tax, then, on the long view, the tax is bad. To this we may add that mathematical and scientific works are notoriously expensive to produce, and that their publication frequently depends on the indirect subsidy afforded by more popular books. There is also another aspect of book sales, a short-term view, which might receive more emphasis; that is, the position of export sales. It is not sufficiently realized how large a proportion of the books produced in Great Britain are sold overseas. The export trade must be maintained, and to this end a healthy home trade is essential, for in no industry more than in book production does final cost depend on the total number of items produced at one working; prospective sales of an edition of 5,000 as against a possibility of disposing of 4,000 copies of a book may enable a publisher to make a substantial reduction in its selling price.

Camouflage in Modern Warfare

Since the publication in Nature of June 22 of the leading article under this title, correspondence has revealed the interest which has been aroused. On p. 168 a letter on the subject, written from the point of view of the artist, demonstrates that scientific workers are not alone in their criticism of the official methods of dealing with camouflage. In this connexion, it is worth while directing attention to an article in the July issue of the *Nautical Magazine*, in which Sir John Graham Kerr discusses camouflage in its application to ships at sea. The article includes a reprint of the original letter drafted by Prof. Graham Kerr, as he then was, and circulated by the Admiralty to the Navy on November 10, 1914, on the use of paint camouflage for diminishing the visibility of ships at a distance. Effective camouflage, whether on land or sea, depends on two fundamental principles: compensative or counter-shading, and parti-colouring or disruptive pattern. The effect of imitative colouring, the basis of the artist's technique, is entirely overborne by the effects of light and shadow.

Sir John points out that complete invisibility by the use of paint camouflage is out of the question. In bright light and a clear atmosphere, it is impossible to hide a large object such as a ship at sea, but in conditions of poor visibility, properly devised camouflage can make it extremely difficult to 'pick up' a ship and can disguise effectively its character, size and course. The trial or adoption of Sir John's suggestions were left to individual flag officers, and this may have accounted for the very indifferent results obtained. In 1917 a modification of these proposals was adopted, under the guidance of Mr. Norman Wilkinson (now president of the Royal Institute of Painters in Water Colours), to which the American biological term 'dazzle' was given, and was widely used for the mercantile marine, American destroyers and certain British war-vessels. As we have already pointed out, present-day methods of paint camouflage are largely ineffective, due in part to lack of co-ordination of the various departments concerned and to lack of scientific direction.

Memorial to Prof. J. H. Ashworth

THE bronze memorial plaque to the late Prof. J. H. Ashworth, a reproduction of which appears on this page, set in Yorkshire monumental stone, was unveiled at Salem Congregational Church, Burnley, by Mrs. Ashworth on June 25. Prof. Ashworth was a Burnley man, and although he spent the last twenty-five years of his life at Edinburgh, he never allowed the link with his birth-place to be broken. As professor of natural history in the University of Edinburgh, he achieved an international reputation, and by his death at the early age of sixty-one on February 4, 1936, the world lost a distinguished zoologist; NATURE lost a valued contributor whose services had extended over many years.

After the unveiling ceremony, at which the Mayor of Burnley presided, addresses were given by, among others, Prof. H. Graham Cannon, professor of zoology in the University of Manchester, and the Rev. T Ormerod, chairman of the Memorial Committee; Dr. W. Howarth, director of education at Burnley and honorary secretary of the Memorial Committee, read tributes received from Sir Thomas Holland, principal of the University of Edinburgh, Sir George Adam Smith, formerly principal of the University of Aberdeen, Sir Richard Gregory, president of the British Association and former editor of NATURE, and others. Prof. Ashworth was a great friend, a great zoologist, and a great teacher and administrator. He was the first in Great Britain to introduce a course of medical zoology, and when the time came to re-organize and build a new department of natural history in the University of Edinburgh, his powers were shown to the full. The building there which now bears his name is a lasting and worthy memorial in the community of his adoption.

Prof. W. P. Alexander

PROF. WILLIAM P. ALEXANDER has been awarded the Cornelius Amory Pugsley Medal of the Buffalo Museum of Science, for his work as a conservationist and naturalist. The medal, established by Chester D. Pugsley of Peekskill, N.Y., in honour of his father, bears the inscription: "Awarded to William Prindle Alexander for his distinguished work as a pioneer of outdoor education in state parks". Prof. Alexander, who is Hayes professor of natural history at the Buffalo Museum of Science, is widely known as a lecturer, writer, and teacher of natural history subjects. He was the originator of the Nature trail idea, his first trail having been planned in the Allegany State Park in 1921; it is now an established institution in many State and Federal parks. Prof. Alexander is a conservationist, not in the sense that he seeks to protect wild life out of season, so that the mute and helpless creatures of wood and field can be indiscriminately maimed and slaughtered 'in season', but as a protector and preserver of all wild life in every season. In addition to being the author of numerous articles on natural history, he has had published several novels.

Dr. Tweedie John Todd

DR. TWEEDIE JOHN TODD, physician and naturalist, was born at Berwick in 1789, the son of the borough treasurer. He studied medicine at Edinburgh and for several years served as a surgeon in the Navy, chiefly in the East Indies and at the Cape of Good Hope, where he made some experiments on the electric ray (Torpedo), which were afterwards published in the *Philosophical Transactions*. He retired from the Navy in 1816, and after spending some years in Italy settled in Brighton, where he soon acquired an extensive practice. He was the author of several papers on natural history which were published in the *Philosophical Transactions* and the *Journal of Science and Arts*, such as "The Regeneration of Parts in the Aquatic Salamander" and "The Luminous Power of Some of the Lampyrides". His contribution to medical literature consisted of "The Book of Analysis. A New Method of Experience", in which he endeavoured to apply Baconian induction to medicine and the other natural sciences. For many years he was engaged in a series of microscopical researches on living animals illustrative of different parts of physiological and pathological science and especially of the processes concerned in the healing and regeneration of wounded and lost parts. He left a large collection of microscope slides at the time of his death, which took place on August 4, 1840.

University Students and Compulsory Service

DR. RAYMOND PRIESTLEY, vice-chancellor of the University of Birmingham, in the course of a circular letter addressed to head masters of a number of schools in the Midlands, has pointed out that the age at which undergraduates will be called up for military service has been fixed by the Government at twenty years. This will enable many men to complete their university training before entering the Services. With the object of enhancing the value of such men to the national effort, it has been decided by the University of Birmingham that all future entrants will be required to choose one of the following options as part of their university course: (1) compulsory physical education for one year; or (2) two years service in the University contingent of the O.T.C. Those who choose the latter will be accepted for the O.T.C. only if they are approved by an interviewing board set up by the Military Education Committee, the main criteria being personality and power of leadership (latent or developed). Training in the O.T.C. will be carried out with the view of developing powers of leadership rather than training technical experts, and should prove of great interest and value to all who join, in whatever walk of life they may afterwards find themselves. The advantages of this general military training apply equally to those taking medical and dental courses, since the military background essential to an R.A.M.C. officer can be adequately acquired in this way. Those who obtain War Certificates A and B will have definite advantages when they are called up for military service; the scheme should go far towards ensuring that the best use is made of all those suitable as officers.

Fire Risk from the Smashing of Filament Lamps

EXPERIMENT shows that it is difficult to cause ignition of combustible material by means of smashing a filament lamp embedded in it. But the lampholder of a large lamp may rise to a fairly high temperature, high enough to explode certain compounds used for military purposes. It is well known that sudden breakage of a glass bulb may occur during heavy gunfire in a battleship or cruiser. It could also happen in a submarine when depth charges are exploding near it. This explains the interest now being taken in the United States Navy in fluorescent lighting for magazines and in other parts of a warship where explosives are handled. It is very difficult to set fire even to cotton-wool by smashing a lighted fluorescent lamp reposing on it.

A useful feature of the mercury fluorescent lamp is that it can easily be so graded as to emit the tone of blue light that is preferred for darkening a ship when in action at night. At present this reduced lighting effect is obtained by shading tungsten filament lamps and using a blue glass bulb, or one which has been sprayed in that colour. The *Electrical Times* of July 4 states that the U.S. Navy is having a series of experiments made with fluorescent lighting, and if it is found that this type obviates the danger due to filament lamps overheating in tropical atmospheres or when they are smashed by heavy gunfire, the mercury discharge type with fluorescent effect may find an extensive use in warships and elsewhere. It is also being recommended for mines, gasworks, petrol and benzine factories, hydrogen plant and all other places where the air is charged with explosive vapours or dust.

Daylight Observation of Venus and Jupiter

DR. A. L. PECK, of Christ's College, Cambridge, writes: "In view of the astronomical notes in NATURE of July 27, p. 128, it may be of interest to record that two planets were picked out here with the naked eye on July 28, at 9.40 a.m. B.S.T.—Venus (daylight observation of which is, of course, nothing unusual) and Jupiter. Observation of the latter was made possible by its proximity to the moon, with which it had been in conjunction a few hours before."

British Museum (Natural History): Acquisitions

THE Zoological Department has received as a donation from Admiral Sir Sidney Bailey, a series of mounted heads of North American ungulates, including a very fine moose and some exceptionally good wapiti and caribou. The collection also contains a head of a Rocky Mountain goat. Another interesting gift to the same Department is a series of ten skulls with horns of African antelopes from the Dinder River District of the Sudan, presented by Mr. T. W. H. Dore. This collection contains, among other specimens, some skulls of Soemmerring's gazelle and of the Sudan race of the roan antelope. The Department of Geology has acquired from the Committee of the Royal Literary and Scientific Institution, Bath, a collection of ninety-nine invertebrate fossils from the Mesozoic of Australia, including a number of type and figured specimens. The Trustees appreciate this recognition of the importance of housing type-specimens, other than those of local interest, in the National Collection.

Beit Memorial Fellowships for Medical Research

A MEETING of the Trustees of the Beit Memorial Fellowships for Medical Research was held on July 17. Prof. A. J. Clark, professor of materia medica in the University of Edinburgh, was appointed to the Advisory Board in succession to Prof. W. Bulloch, who resigned after twenty-nine years service. Dr. Paul Fildes was appointed honorary secretary on the resignation of Prof. T. R. Elliott from that post after ten years service. Out of the twenty-seven present fellows, nine have already been seconded from their fellowships at their own request for more direct service during the War.

The following elections were made, all with permission for each fellow to be seconded at any time for war duties: *Senior Fellowship* (£700 a year): T. A. H. Munro, to continue his studies of inheritance in mental disorders, at the Royal Eastern Counties Institution, Colchester; *Fourth Year Fellowships* (£500 a year): J. G. Chalmers, to continue his chemical studies of polycyclic hydrocarbons in experimental cancer formation, at the Research Department of the Glasgow Royal Cancer Hospital; Dr. T. R. R. Mann, to extend his work on intracellular metallo-protein compounds, especially of red blood cells, at the Molteno Institute of Biology, University of Cambridge; *Junior Fellowships* (£400 a year): M. Abercrombie, junior research fellow, Queen's College, Oxford, to study amputation neuromata and the degeneration and regeneration of mammalian nerves, at the Department of Zoology, University of Oxford; Dr. D. A. K. Black, research student of the Medical Research Council, to study metabolic and bone marrow changes in the repair of severe anæmias, at the Nuffield Department of Medicine, Oxford; Dr. G. C. Butler, 1851 Exhibition science research scholar, to study the purification and properties of gonadotrophic hormone from the pituitary gland, at the Department of Pathological Chemistry, University College Hospital Medical School, London; Dr. J. L. Madinaveitia, honorary research fellow in chemistry, University of Manchester, to study diffusing factors in bacterial filtrates and snake venoms, at the Department of Chemistry, University of Manchester; Dr. S. M. Partridge, Lister Institute student in biochemistry, to study the chemical nature of the antigen of Shiga dysentery bacteria, at the Lister Institute of Preventive Medicine, University of London; D. Whitteridge, demonstrator in physiology, Oxford, to study electrical records from brain after concussion or severe injury, at the Nuffield Department of Surgery and the Department of Physiology, University of Oxford; P. C. Williams, research grantee of the Medical Research Council, to study pituitary hormones and their excretion in clinical pathological conditions, at the Courtauld Institute of Biochemistry, Middlesex Hospital, London.

Announcements

THE Minister of Supply stated in the House of Commons on July 25 that due regard will be had to the provision of reasonable amounts of paper for educational, scientific, and technical publications.

ACCORDING to *Science* of June 28, Prof. Peter Debye, of Berlin-Dahlem, has been appointed professor and chairman of the Department of Chemistry at Cornell University. Prof. Debye has been George F. Baker visiting lecturer in chemistry at Cornell University during the past term. His son, Peter Paul Debye, will be associated with Prof. Debye in research in the Baker Laboratory of Chemistry at Cornell. Prof. Jacob Papish, who has been chairman of the Department, will continue as vice-chairman. Dr. Bruno Rossi, formerly professor of physics in the University of Padua, research associate at the University of Chicago, has been appointed associate professor of physics at Cornell.

IT is announced that the Pétain Government has dismissed M. Huismans, director-general of fine arts, M. Julien Cain, administrator of the Bibliothèque Nationale, M. Laugier, director of the national centre for scientific research, and M. Longchambon, director of scientific research, who are said to have abandoned their posts under the previous French Government without justification.

THE Council of the University of Birmingham has instituted a scheme for family allowances for members of staff whose salaries do not exceed £700 per annum. The allowance, for salaried members, is at the rate of £25 per annum for each child. The wage-earning staff receive an allowance of 2*s.* 6*d.* per week for each child less than sixteen years of age. The scheme takes effect as from February last.

IN 1920, Miss L. Jones-Bateman of Cae Glas, Abergele, presented to the Royal Horticultural Society a valuable silver-gilt replica of the Warwick Vase to be used for the encouragement of fruit production. It is accordingly decided to offer it triennially for original research in fruit culture. Candidates should submit accounts of their work by October 31. The work dealt with should have been mainly carried out by the candidate in the United Kingdom, and mostly during the past five years.

ERRATUM. NATURE, July 20, p. 101, col. 2, paragraph on "Precautions against American Foul Brood in Bees", line 13, for "American" read "European".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Sulphanilamide as a Specific Inhibitor of Carbonic Anhydrase

CARBONIC anhydrase which catalyses the reversible reaction $H_2CO_3 \rightleftarrows CO_2 + H_2O$ is present in large concentrations in the red blood corpuscles and some cells of gastric mucosa of mammals. This enzyme plays an important part in accelerating the carbon dioxide output in the lungs; it appears also to promote the formation of hydrochloric acid by the parietal cells of gastric mucosa[1].

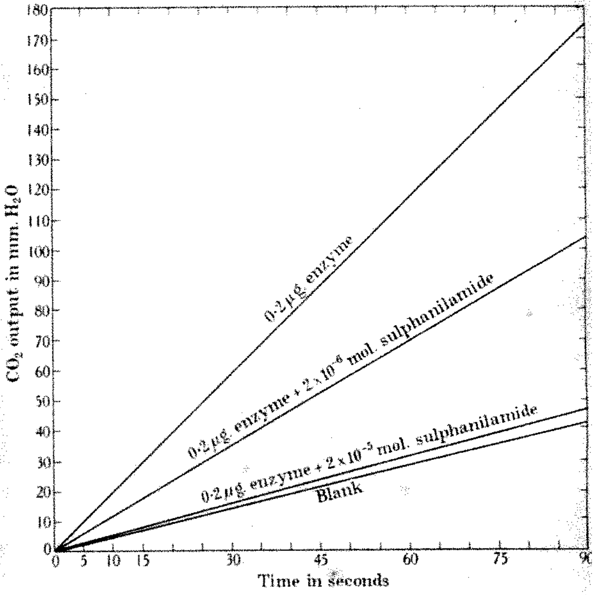
Having isolated carbonic anhydrase in a pure state, we have been able to show that this enzyme is a zinc-protein compound, where zinc forms an essential part of its prosthetic or active group[2,3]. The activity of this enzyme is very strongly and reversibly inhibited by potassium cyanide, hydrogen sulphide and sodium azide. These inhibitors, however, are not specific for carbonic anhydrase, as they are shared also by other metallo-protein enzymes such as catalase, peroxidase, cytochrome oxidase and polyphenol oxidase.

The main object of this investigation was the discovery of new and more specific inhibitors of carbonic anhydrase, as they will certainly be of great assistance in the study of several problems connected with the physiology of this enzyme. The existence of such inhibitors was revealed by the study of some drugs belonging to the class of sulphonamide compounds. The demonstration of the therapeutic efficiency of prontosil and other sulphonamide drugs in treatment of bacterial infections was followed by numerous investigations resulting in an extensive literature dealing with pharmacological and physiological properties of these compounds[4,5]. The repeated references in this literature to the fact that the administration of some sulphonamide compounds is followed by a fall in the carbon dioxide combining power of blood[6,7] suggested the possibility that some of these compounds may have an inhibitory effect on carbonic anhydrase.

This supposition was confirmed experimentally by testing the effect of sulphanilamide on the catalytic activity of carbonic anhydrase in blood, in gastric mucosa and in pure enzyme preparations. The results of these experiments summarized in the figure clearly show that sulphanilamide acts as a very powerful inhibitor of carbonic anhydrase, exhibiting marked effect even in a concentration so low as 2×10^{-6} mol.

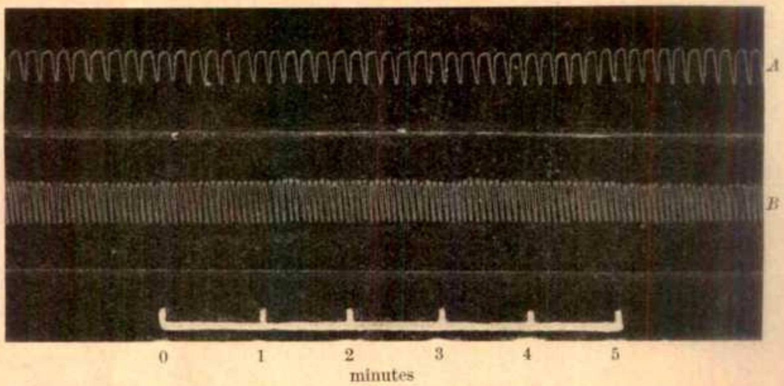
In order to determine which portion of the sulphanilamide molecule (*p*-aminobenzene-sulphonamide $[NH_2C_6H_4.SO_2NH_2]$) is responsible for the action on the enzyme, the effects of a number of other compounds belonging to the sulphonamide group have been tested and the results of these tests can be summarized as follows:

(1) The amino-group of sulphanilamide, which is essential for the therapeutic properties of this compound, is not responsible for the inhibition of the carbonic anhydrase. In fact, its loss as in benzene-sulphonamide $[C_6H_5SO_2NH_2]$, its acetylation as in acetylaminobenzene sulphonamide $[CH_3CONHC_6H_4SO_2NH_2]$ or its shift to *ortho*- or *meta*-positions do not affect in the least the properties of these compounds as inhibitors of carbonic anhydrase.



EFFECT OF SULPHANILAMIDE ON THE ACTIVITY OF CARBONIC ANHYDRASE (TESTED BY MELDRUM AND ROUGHTON METHOD AT 0° C.).

(2) The sulphonamide group appears to be directly concerned with the inhibitory effect of these drugs since the replacement of both hydrogen atoms, or even one in the amido-group, causes a complete loss of the inhibitory property; thus while substances like prontosil $[(NH_2)_2C_6H_3.N{=}N.C_6H_4.SO_2NH_2]$, benzyl-sulphanilamide $[C_6H_5.CH_2NH.C_6H_4.SO_2NH_2]$, pyridine-3-sulphonamide $[C_5NH_4.SO_2NH_2]$ and amino-naphthalene-sulphonamide $[NH_2C_{10}H_6.SO_2NH_2]$ are acting as inhibitors, substances like benzene-sulphonchloride $[C_6H_5.SO_2Cl]$, sulphanilic acid $[NH_2.C_6H_4.SO_2OH]$, sulphanil-acetamide $[NH_2.C_6H_5.SO_2NH.COCH_3]$, Diseptal A $[NH_2C_6H_4.SO_2NH.C_6H_4.SO_2N.(CH_3)_2]$, Diseptal B $[NH_2C_6H_4.SO_2NH.C_6H_4.SO_2NH.CH_3]$, Rodilone $[CH_3CO.NHC_6H_4.SO_2.C_6H_4.NH.COCH_3]$, sulphapyridine (M. & B. 693) $[NH_2C_6H_4.SO_2NH.C_5NH_4]$, pyridine-3-sulphonic acid $[C_5NH_4.SO_2OH]$ and sulphathiazol $[NH_2C_6H_4.SO_2NH.C_4NH_4]$ do not interfere with the activity of carbonic anhydrase. This enzyme therefore appears to be an exceptionally sensitive biological test capable of detecting a few micrograms of an unsubstituted sulphonamide compound.



RATE OF HEART-BEAT OF THE CRESTED NEWT, BOTH ANIMALS AT 0° C. *A*, ACCLIMATIZED TO 30° C.; *B*, ACCLIMATIZED TO 10° C.

(3) Sulphamic acid [NH_2SO_2OH] and sulphamide [$NH_2SO_2NH_2$] inhibit the activity of carbonic anhydrase to a much smaller extent, however, than benzenesulphonamide or sulphanilamide.

As to the mechanism of the inhibition of carbonic anhydrase by these compounds, it is conceivable that the sulphonamide group reacts directly with the zinc-containing prosthetic group of the enzyme. This appears to be supported by the following considerations. The inhibition by sulphonamide compounds does not require a period of incubation, on the contrary it is immediate even at low temperatures, it is also very strong and completely reversible. In this respect it shows great resemblance to inhibitions produced by reagents such as potassium cyanide, hydrogen sulphide and sodium azide which are known to react with metals. Both sulphamic acid and sulphamide are known to form compounds with metals. Moreover, benzene-sulphonamide, like some other acid amides, reacts with alkaline metal-amide compounds including zinc-amide[8,9].

The experiments which we have carried out in order to determine the effect of sulphonamide compounds on other enzymes have shown that even in concentrations as high as 10^{-2} mol. they have little or no effect on enzymes such as catalase (purified preparation from liver), peroxidase, cytochrome oxidase, polyphenol oxidase, xanthine oxidase, uricase, urease and carboxylase.

The inhibitory effect of sulphonamide compounds on carbonic anhydrase appears to be highly specific. These inhibitors therefore make it possible to abolish the activity of carbonic anhydrase in cells and organisms without affecting the activity of other known catalytic systems.

For the gift of several substances used in this investigation we wish to thank Dr. H. King, Dr. T. A. Henry, Dr. H. McIlwain, Dr. W. J. C. Dyke of the Evans Biological Institute, May and Baker, Ltd., and Schering, Ltd.

Temperature Coefficients and Acclimatization

CERTAIN biologists (especially Crozier[1] and his school) have formulated theories on the effects of changing temperatures on protoplasm. The numerical value of the temperature coefficient $\left(= Q_{10} = \dfrac{\text{velocity at } (t+10)^\circ\text{ C.)}}{\text{velocity at } t^\circ\text{ C.}}\right.$ of a biological reaction is believed to afford a clue to the nature of the controlling physical or chemical changes. I consider that theories based on such evidence may often be misleading.

I showed recently[2,3] that the position of the chill coma temperature (that is, the highest temperature at which immobilization occurs) for insects and Amphibia is not rigidly fixed but may be altered many degrees by first acclimatizing the animal—and acclimatization is usually complete within as short a period as twenty-four hours—to a high or a low temperature. Not only is the chill coma temperature affected, but the reactions of some tissues may be modified also. In the case of the crested newt, *Triton cristatus*, animals from stock were acclimatized to 10° C. and 30° C. by exposure to these temperatures for twenty-four hours, they were then immersed in water at 0° C. or 10° C. and the rate of heart-beat determined. Results are given in the table. In the accompanying figure tracings from two newts differently acclimatized and then both cooled to 0° C. are shown.

NUMBER OF HEART-BEATS OF THE CRESTED NEWT PER MINUTE.

	Acclimatized to 10° C.	Acclimatized to 30° C.
At 0° C.	14	6
At 10° C.	25	16

If all these results are considered, and the fact that some of the animals were differently acclimatized is, for the moment, neglected, four values of the temperature coefficient may be obtained, namely, 1·1, 1·8, 2·7, 4·2. The two extreme values (1·1, 4·2) are mainly of interest because certain other workers have not ensured that all their animals came from identical conditions; the results of such experiments will be difficult to interpret. The other values of the temperature coefficient of the newt's heart over the range between 0° C. and 10° C. show that the acceleration for an animal acclimatized to 10° C. ($Q_{10} = 1 \cdot 8$) might be assumed to be controlled by a physical 'master reaction', while that in the one acclimatized to 30° C. ($Q_{10} = 2 \cdot 7$) the controlling reaction would be thought to be of a chemical nature.

Such explanations appear to me unsatisfactory. The reasons for the increase in velocity of almost any biological reaction with an increase in temperature are very imperfectly understood; these observations on acclimatization may eventually help in the formulation of a satisfactory explanation.

At every temperature some acclimatization is probably going on in a living tissue, the extent of the acclimatization depending partly on the length of the exposure. This appears to me to mean that at any particular temperature there may be no absolute rate for a biological process, and that all conditions previously experienced by the animal must be considered. Otherwise any theory based on the speed of a reaction must be treated with great caution.

Evidence of Demethylation in the Animal Body

DURING the course of work on the metabolism of synthetic œstrogenic compounds[1] undertaken at this Institute, attention has been directed to the methyl ethers of some of the synthetic œstrogenic phenols. Preliminary experiments have been carried out on 4 : 4′-dimethoxy diphenylether and 4-methoxy diphenyl; 4 : 4′-dihydroxy diphenylether having been shown to produce full œstrous response when injected at a dose of 100 mgm. into ovariectomized rats, and 4-hydroxy diphenyl shown to have no œstrogenic activity at a dose of 100 mgm.[2]

3 gm. of 4 : 4′-dimethoxy diphenylether, dissolved in sesame oil, were injected into two female rabbits over a period of three weeks, the urine being collected during this period and for a further week after the last injection. From the 'free' and 'combined' phenolic extracts prepared from the urine a crystalline phenol was obtained by repeated extraction with boiling water, 47 mgm. occurring in the 'free' state and 22 mgm. in the 'combined' state. After several recrystallizations from petroleum ether this phenol melted at 90° C. and was shown to be 4-methoxy-4′-hydroxy diphenylether.

3 gm. of 4-methoxy diphenyl were injected into two rabbits in the same way as above, and a crystalline solid obtained from the 'free' and 'combined' phenolic extracts prepared from the urine, 203 mgm. occurring in the 'free' state and 43 mgm. in the 'combined' state. After several recrystallizations from benzene 30 mgm. of a crystalline phenol m.p. 268° C. were obtained and shown to be identical with 4 : 4′-dihydroxy diphenyl m.p. 272° C. From the benzene mother liquors 111 mgm. of another crystalline phenol m.p. 162° C. were obtained and shown to be identical with 4-hydroxy diphenyl, m.p. 163° C.

These results show that demethylation definitely occurs in the animal body and gives support to the suggestion made by Westerfeld[3] that œstrone methyl ether is metabolized in the body to œstrone.

Work on the metabolism of the methyl ethers of the highly active synthetic œstrogenic phenols is now in progress.

Resonance in the Chloroacetic Acids

IN a recent letter[1], H. O. Jenkins has made the interesting suggestion that the high acid dissociation constants of di- and tri-chloroacetic acids are largely due to the possibility of a resonance structure in their anions. It is the purpose of this note to indicate a possible means of testing this hypothesis.

The strengths of acids or bases are in general a good measure of the velocity with which they will lose or gain protons. This is shown by the wide validity of relations of the form $k = GK^{\alpha}$, where k is the velocity of a catalysed reaction, K the strength of the catalysing acid or base, and G and α constants for a given solvent, temperature and reaction[2]. However, this parallelism will break down if the acid and base involved in the equilibria used for defining acid-base strengths have different electronic structures. The extreme case of this behaviour is met with in pseudo-acids, where the charge on the anion may reside on an atom other than that from which the proton has been removed (for example, $CH_3NO_2 \rightarrow CH_2 : NOO^- + H^+$). This point was realized by Brönsted when he first proposed quantitative relations of the above type, and it was in fact shown that in the decomposition of nitramide the ions of pseudo-acids had a much smaller catalytic effect than would be predicted from their dissociation constants[3].

The same type of argument applies in general to cases where resonance structures occur in only one member of an acid-base pair. In the case of dichloroacetic acid, let the 'normal' molecule and ion be denoted by H*A* and *A*⁻, and the resonance structures  $\genfrac{}{}{0pt}{}{\text{Cl}}{\overline{\text{Cl}}}\!\diagdown\!\!\diagdown\overset{+}{\text{C}}\text{H.COOH}$ and  $\genfrac{}{}{0pt}{}{\text{Cl}}{\overline{\text{Cl}}}\!\diagdown\!\!\diagdown\overset{+}{\text{C}}\text{H.COO}^-$ by H*R* and *R*⁻. Let us suppose for the sake of simplicity that the molecule exists almost entirely as H*A*, and the ion almost entirely as *R*⁻. The best measure of the tendency of H*A* to lose a proton is given by the constant $[H^+]\,[A^-] / [HA]$, which is much smaller than the observed dissociation constant $[H^+]\,[R^-] / [HA]$: hence the dichloroacetic acid molecule will be a less powerful acid catalyst than would be expected from its dissociation constant. Similarly, the tendency of *R*⁻ to pick up a proton is represented by $[HR] / [H^+]\,[R^-]$, which is smaller than the observed constant $[HA] / [H^+]\,[R^-]$: hence the dichloroacetate ion will be a less powerful basic catalyst than would be expected from the dissociation constant of the acid. In a catalytic reaction involving dichloroacetic acid or its ion, the transition state will actually be intermediate in structure between *A* and *R*, but the same qualitative conclusions will apply.

There is a certain amount of experimental evidence for the existence of this effect. Thus in the iodination of acetone[4], the catalytic effect of dichloroacetic acid is about 30 per cent lower than the value calculated from an equation based on seven other carboxylic acids (average deviation 8 per cent). Similarly, in the decomposition of nitramide[3,5,6], the catalytic effect of the dichloroacetate ion is 35 per cent lower than the calculated value (based on twelve other anions: average deviation 4 per cent). There appear to be no other cases for which sufficiently full or accurate data are available.

These results lend some support to the view that a resonance structure plays a part in the dichloroacetate ion. On the other hand, the effects observed are smaller than might be expected if resonance is a major cause of the thirty-fold increase of dissociation constant in passing from $CH_2Cl.COOH$ to $CHCl_2.COOH$.

Mechanism of the Neutron Loss Reaction Produced by Deuterons

IN a recent letter in NATURE, Krishnan and Banks[1] reported an interesting new type of nuclear transformation. Copper, consisting of two stable isotopes 63 and 65, was bombarded with deuterons, and the radioactive isotope Cu^{62} (10·5 min.) was obtained. The transformation was found to have a threshold at a deuteron energy of about 7 Mev. By analogy with the well-known reaction

$$Cu^{63}\ (n-2n)\ Cu^{62}, \qquad (1)$$

Krishnan and Banks suggested that a new kind of neutron loss reaction might explain their results, either

$$Cu^{63}\ (d-d, n)\ Cu^{62}\ (2), \quad \text{or} \quad Cu^{63}\ (d-p, 2n)\ Cu^{62}\ (3)$$

From some further observations they concluded that reaction (3) was more probable. In a similar way they interpreted previous results of Krishnan and Gant[2], who had found that Ag^{107} could be transformed by 9 Mev. deuterons into Ag^{106} (26 min.). For this case, however, the threshold energy has not yet been determined.

Recently, in the course of an investigation of the radioactivity produced when beryllium is bombarded by deuterons, a different type of neutron loss reaction was established in this laboratory[3], namely, the reaction

$$Be^{9}\ (d-H^{3})\ Be^{8}.$$

It seemed, therefore, worth while to examine the possibility that the effect reported by Krishnan and Banks might be due to the analogous reaction

$$Cu^{63}\ (d-H^{3})\ Cu^{62} \qquad (4)$$

If we denote by $E\ (D^2)$, $E\ (H^3)$ and $E\ (Cu^{63})$ the energies necessary to remove a neutron from D^2, H^3 and Cu^{63} respectively, and by $E_1, \ldots E_4$ the threshold energies of reactions (1) . . . (4), we obtain the following simple relations.

$$E_1 = E_2 = E\ (Cu^{63}),\ E_3 = E\ (Cu^{63}) + E\ (D^2),\ E_4 = E\ (Cu^{63}) - E\ (H^3).$$

The threshold energy of reaction (1) has been measured by Sagane[4], who found a value between 12 and 13 Mev. His work has been confirmed by Salant and Ramsey[5], who find a value close to 12 Mev. We shall adopt for the following the value $E_1 = 12$ Mev. The binding energy of the deuteron is known, $E\ (D^2) = 2{\cdot}2$ Mev. $E\ (H^3)$ can be easily calculated from the masses of H^3, D and n. We find, using Barkas' compilation of masses[6], $E\ (H^3) = 6{\cdot}2$ Mev.

With these values we obtain for the threshold energies of reactions (2, 3, 4)

$$E_2 = 12\ \text{Mev.},\ E_3 = 14{\cdot}2\ \text{Mev.},\ E_4 = 5{\cdot}8\ \text{Mev.}$$

It appears that the $(d-H^3)$ reaction (4) can best account for the observed threshold of about 7 Mev.

If we assume that a $(d-H^3)$ process takes place according to the 'compound nucleus' model of nuclear reactions developed by Bohr, it appears difficult to understand why the reaction is observable with a nucleus of so high an atomic number as $Z = 29$ (Cu) or even $Z = 47$ (Ag). For, with deuteron energies below 9 Mev.[1,2], the H^3 particle will be emitted with an energy considerably below the top of the potential barrier, and consequently, once the highly excited compound nucleus is formed, the probability of emission of an H^3 article will be quite negligible compared with the probability of emission of a neutron or proton. It would seem preferable, therefore, to picture the $(d-H^3)$ reaction without postulating the formation of a compound nucleus. We would then have to assume that a deuteron with an energy exceeding the threshold could capture a neutron in a collision with the nucleus without entering it. Near the threshold, the Coulomb force between the final nucleus and the H^3 particle would lead to a very small probability of the $(d-H^3)$ reaction. This might account for the fact that the lowest deuteron energy at which the production of Cu^{62} was observed[1] is higher than the calculated threshold of reaction (4).

Viscosity and Molecular Structure

TABLE 2 of our recent article in NATURE on "Viscosity and Molecular Structure"[1] contains some molecular weights of nitrocellulose and cellulose acetate estimated from viscosity measurements. One sentence of the text referring to this table runs: "in this case no experimental data from the ultracentrifuge were available".

Dr. E. O. Kraemer has been so kind as to direct our attention to the fact that (although the samples to which reference is made in the table have not been directly investigated by the ultracentrifuge) a number of other nitrocelluloses and cellulose acetates have been investigated by him[2] and by R. Signer[3] with the aid of the ultracentrifuge. We are greatly indebted to Dr. Kraemer for this comment, and wish to correct the remark in our article by adding: Ultracentrifuge measurements by E. O. Kraemer[2] gave, for cellulose acetate and nitrocellulose, molecular weights between 50,000 and 250,000 and between 102,000 and 160,000 respectively. It is also of importance to add that Dr. Kraemer, Dr. Signer and their collaborators have measured methyl and ethyl cellulose and have found values of 14,000–38,100 and 125,000 respectively.

Concerning the shape of proteins, data and formulæ presented by J. W. Mehl, J. L. Oncley and R. Simha[4,5] give better agreement between results obtained by viscosity measurements and those provided by the ultracentrifuge than that shown in Table 1.

Finally, we owe to Dr. Kraemer the information that the viscosity behaviour of gelatin at 34° investigated by Sanigar, Krejci, and Kraemer[6] is irreconcilable with the sedimentation constants, if the gelatin particles are assumed to be solvated spheres. The necessary degree of solvation would practically eliminate the difference between the densities of particle and medium.

Camouflage in War-time

THE article on camouflage in NATURE of June 22 provides ample evidence of incompetence in this subject, but the writer has turned his guns in the wrong direction. His attack on artists has little relation to fact, in that the vast mass of 'camouflage' visible in all its glorious futility on army vehicles and buildings is not the work of artists.

A few weeks after the declaration of war a fellow artist, Mr. F. S. Manner, and I submitted a memorandum to the War Office camouflage authorities which covered all the criticisms mentioned in the article and a great many more. We are aware of at least one other memorandum on similar lines also submitted by an artist. We stressed the importance of biological study which, I am afraid, we called "Nature study", while pointing out the many occasions when it would be quite inapplicable. We also gave what we consider a practical solution to the whole question of co-ordination and control.

We also approached a Government contractor in relation to structural camouflage, and after some inquiry, he informed us that much of the work was in the hands of the Paint Manufacturers' Association. If this is so, it may be one of the reasons why khaki and green lozenges, of equal tone value, appear like a rash on everything that moves or stays in the military field. The artists at the Camouflage Research Station are probably equally sceptical about the situation, but what artist since the dawn of time has not obeyed the voice of the Philistine or said good-bye to his wage packet ? There is a strong case for employing display and exhibition artists rather than those accustomed to landscape and other forms of painting, because the former are used to designing structurally, and experts in getting almost any effect with the minimum material.

The artist should not be blamed for the present situation, however, because he is only too willing to co-operate with the biologist ; indeed he is no mean naturalist himself. Leonardo da Vinci, a great artist and scientist, pointed out Nature's use of protective colouring before Thayer was born. Artists before and since have been fully aware of the principles of 'countershading', 'coincident pattern', 'disruption', and 'deflection', only they have been called in art schools since the time of Rembrandt such other names as 'counterchange', 'discord and harmony', 'atmospheric and solid perspective'. Indeed, it is impossible to paint a picture without using these principles. Incidentally, no mention is made of the importance of aerial photography, which by using special film nullifies the virtue of colour, whether put on by naturalist or artist.

Let men of science turn their righteous indignation (an emotion impossible to the twisted cynicism of the artist) in the direction of the bureaucrats responsible for the control of camouflage. They will find the artists dour warriors in the same cause.

Cobalt and Pine Disease

IN a recent communication[1] Stewart and Ponsford have questioned the justification for our claim regarding the value of cobalt in the control of pine disease in sheep. We have examined the results which they have published[2], but find no evidence that they effect the validity of our conclusions.

It is unnecessary to go into details here, for a summary of the work carried out on the Scottish side of the border appeared last year[3] and shows that the use of cobalt for curative and preventive purposes has been widely adopted in the south of Scotland and in other areas with highly successful results. On farms where the treatment has been introduced on a systematic scale pine disease has been abolished. We have treated more than three hundred pining sheep by oral administration of cobalt on many different farms and the rate of recovery has been 97 per cent. The same treatment has been given by stock owners on the farms concerned with similar results. Sheep to which cobalt chloride has been administered have been kept for two years on pining land without a change of pasture and have remained entirely healthy.

Whatever may be the cause of this disease known as 'pining' on the Scottish borders, there now seems to be ample evidence that small doses of cobalt can cure or prevent it. It is possible that the experiments carried out by Stewart and Ponsford in Northumberland have been conducted under conditions which have become abnormal and have led to complications so that the use of cobalt alone is unavailing.

RESEARCH ITEMS

Amerindian Religious Reactions to Cultural Impact

In a study of the ghost dance, which appeared among the Indians of Oregon and California in 1870, Cora Du Bois points out that it is a minor phase of a recurrent series of Messianic or revivalistic movements which have arisen among the weaker peoples throughout the world as reactionary waves to the crushing impact of European culture (*Anthrop. Rec.*, 3, 1; 1939. California Univ. Press). The ghost dance cult originated among the Paviotso of Walker Lake in Nevada in 1869–70; and from it developed a complicated series of cults during the sixty years beginning in 1871. The early manifestation consisted largely of doctrinal stress on the return of the dead and the end of the world, which in some vague supernatural way would entail the elimination of the white people. The ghost dance proper had two main strands of diffusion. Among the Wintun and Hill Patwin a further development was what is known as the earth lodge cult from its most characteristic feature. This cult stressed the end of the world. The faithful were to be protected from the catastrophe by the subterranean houses which they built for the purpose. Like the original ghost dance, this cult had two main strands of diffusion. An elaboration was the Bole-Maru, which abandoned the doctrines of imminent world catastrophe and stressed instead a concept of the after life and of the supreme being. Ceremonially its highest development occurred among the Patwin and Pomo. Each local dreamer had his own revelations and supernatural authority, which determined the form his cult activities should take. A probable dating indicates the origin of the ghost dance in 1869–70, diffusion beginning 1871, earth lodge cult 1871–72, Bole-Maru in its first form 1872, persisting, though in a state of flux, down to the present day.

Shrine and Market in Morocco

The saintly shrine of Sidī l-Yemām, a few miles south-east of Azila on the Laraiche-Tetuan road, typical of many in the countryside of Morocco described by Walter Fogg in *Man* of July, has a close relation to the nearby tribal market. The saint is said by tradition either to have come to Morocco with the founder of the first Mohammedan dynasty, or to have been a fighter against the infidel. Though his body lies in the grave, he is thought also to be alive. He is the patron of the countryside, and every year after the wheat harvest and threshing an important festival is held at the shrine in his honour, when much dancing, powder-play and feasting take place. Around the shrine is a large grove of old olive trees, each of which has much *baraka* (literally 'blessing', a wonder-working force). On certain of the trees fragments of clothing are tied as a means of placing *ar* on the saint, that is, the conditional curse which serves as a means of securing the fulfilment of a wish. The grove is also a haven of refuge. The spring is a 'haunted' and also a 'safe' spring, as opposed to a spring haunted by evil spirits. The tortoises, leeches and eels of the spring were 'holy', while the frogs, though not holy, might be inhabited by good spirits. Sacrifices were made at the spring as well as at the shrine itself, which was also the place at which solemn oaths were taken either between individuals or the representatives of two tribes after an intertribal war. In addition to the general significance of the shrine in relation to tribal life, which affected the market also, it had a particular reference for the latter. Not only was the spring the water supply of those attending the market—and holy at that; but also the market was under the special blessing of the saint, who walked about in the form of a visitor, or invisible, and his *baraka* protected buyer and seller alike. Everything bought at the market contained much *baraka* and might increase greatly in quantity after being stored, while the health and happiness of those attending will become greater from the influence of the saint.

Anti-Pernicious Anæmia Principle in Urine

In normal gastro-hæmopoiesis at least three unidentified factors appear to be involved. These are: (1) the 'intrinsic' factor of Castle or the 'hæmopoietin' of Wilkinson and Klein, which has enzyme-like properties and is present in the mucous membrane and secretion of the stomach and pylorus and reacts with (2) the 'extrinsic' factor of Castle such as beef protein, producing (3) the anti-pernicious anæmia principle absorbed from the intestine and stored chiefly in the liver. J. F. Wilkinson *et al.* (*Biochem. J.*, 34, 698; 1940) have now shown the anti-pernicious anæmia principle may be isolated from normal male urine or from urine of treated patients with remitting pernicious anæmia but not from urines of untreated relapsing cases of pernicious anæmia. The extracts, active by intramuscular injection, were obtained by either concentrating the urine by evaporation and precipitating inert material with alcohol or by adsorption of the active material on norite at *p*H 5. It is pointed out that if an accurate chemical or biological test for the anti-pernicious anæmia principle becomes available, by which relatively small amounts of urine can be assayed, then such a test may be of great value in the early diagnosis of the disease, since absence of the principle from the urine should be one of the first signs long before the blood picture becomes characteristic. It seems reasonable to suppose that the principle present in the urine is identical with the liver principle, and represents that which has been removed via the kidneys from the blood.

Corals of the John Murray Expedition

Vol. 6, No. 5 of the *Scientific Reports of the John Murray Expedition*, 1933–34, British Museum (Natural History), 1939, is noteworthy in having a special part (B) on the ecology of the solitary corals by J. Stanley Gardiner, besides Part A on the Madreporaria, excluding Flabellidæ and Turbinolidæ previously described, by the same author with Peggy Waugh. It is seldom that so full a statement is available of the difficulties which are encountered by the systematist when the group dealt with is subject to such extreme variation and so many environmental factors are involved. To determine the specific and even generic characters of these corals is a heart-breaking task, but one which has been much helped in the present instance by the large number of specimens of certain forms in the collection and a fair series of many, allowing a study of environmental variation in the species and a determination as to the characters which may be regarded as specific. Thirty-six species and sixteen genera are represented. Stress is laid on the fact that we do not yet know how the corallum is formed and the urgent need of this knowledge. A plea for the closer collaboration between geologist and biologist closes this interesting, if pessimistic, essay.

Taxonomy of the Actinomycetes

Two papers by E. Baldacci, relating to the systematic positions of ray fungi or Actinomycetes, have recently appeared in *Mycopathologia*. The first ("Introduzione allo studio degli Attinomiceti", vol. 2, fasc. 2, July 1939) is a comprehensive study of the whole family. A historical review of classification within this group reveals the need for a modern taxonomic framework to accommodate the research findings of recent years. This is met by a new classification, where the Actinomycetales are divided into two families with amended range, namely, Mycobacteriaceæ and Actinomycetaceæ. The former is further subdivided into Leptotrichioideæ and Proactinomycoideæ. Prof. Baldacci also proceeds to the finer divisions of classification in a further paper (vol. 2, fasc. 3; March 1940), where ten species of the genus Actinomyces are considered critically in the light of morphological and cultural behaviour. Subdivision into species has formerly been carried to excess, and several species described as new are now shown to be really strains of well-established specific conceptions.

Variegation in *Nicotiana Tabacum*

Among the monosomics (23II + 1) of *N. Tabacum*, the haplo-*C* type has been found to produce new types of the form 23II + C_1 + a fragment. These fragments are translocation products of the *P* and *C* chromosomes. The flower colour gene *Wh* is situated on the *C* chromosome. In an exceptional plant with flowers variegated carmine and white some cells contained 23II + C_1 + a fragment, while in others the fragment was missing. By propagating parts of the plant by the aid of hetero-auxin, K. R. Stino (*J. Hered.*, 31, 19–24; 1940) was able to show that the fragment was a ring-chromosome. Different cells contained rings of different sizes, or more than one ring. The behaviour of the ring-chromosomes appears to be, in general, similar to that of McClintock. The carmine-white variegation, therefore, is presumed to result from the loss of the *Wh* gene by breakage and deletion during the division of the ring-chromosome and sometimes to elimination of the ring-chromosome during mitosis. Sometimes the carmine sections were more intense than normal; this may be due to the presence of a double dose of the *Wh* gene. It is interesting to note that Clausen has now shown that the fragment in the classical case of the carmine-coral variegation is ring-shaped.

Colchicine Treatment of Daphnia

H. Howard Durham and A. M. Banta (*Genetics*, 25, 310–328; 1940) treated parthenogenetic eggs of a control line of *Daphnia longispina* with dilute solutions of colchicine. 60 unusual individuals occurred in 1748 treated eggs. Of these, 33 showed no ovarian activity, 20 produced parthenogenetic eggs which failed to hatch, while seven gave rise to mutant clones. Three of these mutant clones reverted to normal after several parthenogenetic generations. None of the eggs hatched from one line which was induced to reproduce sexually. There was no evidence of polyploidy, and the nature of the changes brought about by colchicine in Daphnia await further elucidation.

Temperature Distribution in the Lower Stratosphere

A discussion entitled "Distribution of Temperature in the Lower Stratosphere" by M. W. Chiplonkar deals with the increase of temperature with height that has been observed in India between heights of about 18 and 25 kilometres (*Proc. Ind. Acad. Sci.*, **11**, No. 1, Sec. A; 1940). The India Meteorological Department has been very successful in obtaining observations of temperature at great heights, and the author had for his purpose ten soundings from Poona (latitude 18°) and sixteen for Agra (latitude 27°). All except four of these twenty-six ascents were made during the period November–April, and many at such a time that the sun was probably below the horizon when the balloon passed into the stratosphere. These last must therefore have been unaffected by solar radiation. It appears that no other country can show a comparable number of very high soundings free from this only too likely source of error. The increase of temperature between 18 and 25 kilometres over Poona is largest around 21 kilometres, where it amounts on an average to between 4° and 5° C. per kilometre. It appears to be a permanent feature of the stratosphere over tropical India. Comparison is made with Munich (48° N.) and Abisko (68° N.), where an analogous rise is shown; but one which begins at a lower level, is much smaller, and is confined to the summer half of the year. The view is taken that in those European ascents that were made with the sun above the horizon the variation of temperature with height was probably little affected, although the level of temperature probably was affected. A short summary of some present-day views about the causes of the distribution of temperature within the stratosphere is added.

Investigation of the Period of RW Sagittarii

P. M. Ryves has discussed his observations of RW Sagittarii since 1923 (*Mon. Not. Roy. Astro. Soc.*, 100, 6; April 1940). Ryves suggested in 1923 (*Mon. Not. Roy. Astro. Soc.*, 84, 34; 1923) that it was a variable star of long-period type and small amplitude, the extreme range being 2·1 magnitudes and period 188 days. Although a large portion of his observations from 1923 is inaccessible owing to the international situation, it has been found possible to discuss some provisional data. From a re-examination of the earlier work in conjunction with some of the later observations, it seems that the period of 188 days satisfies the observations up to 1926 or 1927. After 1926 the observed dates of minima commenced to lag behind the calculated dates by increasing quantities, and a period of 191 days satisfied the later observations, but greater precision will not be attempted nor will the light-curve be fully described until all the observations can be used, The change of period appeared to have been effected abruptly about cycle 30 or 31 (1925–26), and about this time the light-curve showed peculiar irregularities, including indications of a second wave or inflection with a period of about 172 days, and a superimposed short-term variation, period 22 days.

THE ROYAL SOCIETY OF CANADA

ANNUAL MEETING

THIS year the fellows of the Royal Society of Canada were the guests of the University of Western Ontario in London, for their annual meeting during May 20–22. The attendance was not so large as last year; but representatives from all parts of Canada attended and presented papers. The University buildings, situated in beautiful spacious grounds outside the city, presented a peaceful contrast to the present conditions in Europe.

The presidential address, "A Study of the Organization and Work of the Royal Society of Canada", was delivered by Dr. H. M. Tory, following a complimentary dinner tendered the fellows, their wives and guests, by the City of London on May 20. The president stated that the Royal Society of Canada differs in one respect from the similar Society in England, in that it includes under its organization all the intellectual movements which were deemed worthy of recognition. Thus with the Natural Science Sections III, IV and V are associated the Literary Sections including philosophy, literature, history and economics. After outlining the various contributions of the older sciences and literary fields of knowledge to our present Western society, Dr. Tory concluded with the suggestion that they should at their annual meeting each year have a major symposium dealing in some form with the relations existing between the various sections. Two typical topics suggested were the effect of science upon literature in the last hundred years and the present state of controversy between science and philosophy.

On May 21, Dr. R. W. Boyle received the Flavelle Medal of the Society for distinction in scientific subjects, in recognition of his researches, particularly on the development of 'Asdics' and his work on ultrasonics. The presentation of the medals was followed by a scholarly lecture delivered by Dr. F. Cyril James, principal of McGill University, on "Science and Society", in which he traced the changes in Western society brought about in the four centuries between 1475 and 1875 due to the impact of scientific discovery. He pointed out that the primary function of the social sciences is the charting for society of a course that is most appropriate in the light of the existing fund of human knowledge. Apparently the impact of science on society has not been wholly beneficial; the ethos of Western society has not responded to the changes in its material environment, but if we are willing to face the major problem of deciding upon our ideals, the forces that science has placed at our disposal are sufficient to make the attainment of those ideals a practical possibility.

Section III (Chemical, Mathematical and Physical Sciences) was held under the presidency of Prof. J. A. Gray, who delivered the presidential address on "Studies in Beta and Gamma Rays", in which he outlined the early work done in Rutherford's laboratory at Manchester and the subsequent development of the theory of scattering and softening of the γ-rays on passing through matter. Recent experimental results on the beta-ray spectra and the gamma-rays from uranium X were presented by Dr. Gray. Five new fellows were elected to the Section: Dr. A. N. Campbell, Prof. P. E. Gagnon, Prof. Gordon Pall, Dr. R. M. Petrie and Prof. H. Grayson Smith.

Of the eighty-four papers presented to Section III, twenty-five were by title. Dr. S. A. Hodgson described the seismograph installation at the Lake Shore Mines, Kirkland Lake, Ont., and the results obtained in investigating the possibility of forecasting the rock bursts which are prevalent in that mine. The results of experiments on the vibrations in aircraft, described by Dr. D. C. Rose, indicated the possibility of improvement in the design of such craft. Dr. J. S. Foster reported that he and his associates had obtained some new results in the Stark effect, using copper, nickel, mercury, zinc, cadmium, and lead, and fields from 100 to 250 kv./cm. R. G. Elson, Grayson Smith and J. O. Wilhelm described a new type of calorimeter for determining the specific heats of materials at liquid hydrogen temperatures. Among the results communicated, it was stated that the variation with temperature of the specific heat of manganese can be expressed by a Debye function with a characteristic temperature of 410° and a linear term $0{\cdot}0042\,T$.

A very interesting investigation on the validity of the Ferry-Porter law in normal, enhanced and depressed states of visual sensibility, and the influence of stimulation of the senses of vision, hearing, taste and smell upon the sensibility of the organs of vision were reported by Dr. Frank Allen. It appears that stimulation of one sense causes a periodic rise and fall in another, the results confirming and extending the work of Kravkov. For example, stimulation of the ear by sounds makes red colours appear dimmer and green brighter when no rest interval is allowed, but after a rest interval of three minutes, the red appears brighter and the green dimmer. A number of papers on meteorology by the staff of the Meteorological Office were communicated by the director, John Patterson, who exhibited a new *radio-sonde* instrument by R. C. Jacobsen, now being used by the Service. Dr. L. Gilchrist described geophysical results of electrical drill hole coring carried out with the assistance of A. R. Clark, and Dr. D. A. Keys gave the results of a magnetic survey on Calumet Island. Dr. D. K. Froman described a 12-inch cloud chamber used in a magnetic field for the study of cosmic-ray mesotrons.

Among the fourteen mathematical papers read, Dr. Buchanan spoke on second genus crossed orbits, in which he considered a special case of the restricted three-body problem. Dr. R. L. Jeffery gave a paper on the integration of functions in a complete normed sector space, in which he set forth a theory equivalent to that of G. Birkhoff.

Dr. Gordon Pall delivered a paper on "Simultaneous Representation in Quadratic and Linear Forms", and among several papers read by Prof. Synge attention is directed to a new electromagnetic energy tensor. A direct application of the laws of conservation of energy and momentum leads to the equations of motion given by the Lorentz ponderomotive force, without the radiation term. Dr. W. L. G. Williams communicated the results of an investigation on hyperbolic trigonometry.

In the Chemistry Section, Dr. E. W. R. Steacie and his students presented five papers on photosensitized reactions, in which the polymerization of ethylene was investigated using different wave-lengths in the ultra-violet, and an estimate of the strength of the C–H bond was determined. Dr. P. Gagnon described the synthesis of some new hydrocarbons in the indene series, and Dr. R. H. F. Manske described the structure of hunnemanine. A large number of papers were read by Dr. R. H. Clark and his students. An examination of the phenolic constituents of the water-soluble ethanolysis products of western red cedar, Douglas fir and western hemlock was made, and the oil isolated from the phenolic constituent in each case on methylation with diazomethane yielded a white crystalline compound with the same melting point as that from spruce and maple woods. Another paper described a method for the synthesis and isolation of glycuronic acid.

Prof. Otto Maass was elected president of Section III and Prof. J. K. Robertson secretary.

The feature of the meetings in Section IV (Geological Sciences) was the excellent address of the president, Prof. J. J. O'Neill, on "The Exploitation and Conservation of Mineral Resources in a Balanced Development of Canada". He urged that while the mines are active in Canada's north, bringing men and money into the country, is the time to take preliminary steps toward permanent settlement; otherwise when mines are exhausted the settlements will be deserted and become 'ghost towns'. Each district will have to be considered as an individual problem, and study of these problems should be begun at once. Agriculture in the few areas possible, reforestation to be followed eventually by scientific lumbering, and the development of manufacturing industries near sources of power were some of the possibilities suggested.

Among the twenty-eight papers presented, special mention may be made of one by P. M. Hurley, C. Goodman and R. D. Evans on the investigations of the helium method of age determination. They show that the agreement between the results obtained using samples of pyroxene from specimens is much better than that obtained from determining the age from felspar. It is suggested that pyroxene retains its helium and is more suitable for such age determinations. Dr. A. E. Gill directed attention to the unsatisfactory state of fault nomenclature and suggested certain improvements. As a result, a committee was appointed to study the question and report at the next meeting. J. T. Wilson summarized the results of a study of air photographs covering a large belt of the North-West Territories. The investigation showed this part of the Canadian Shield to be a mosaic of fault blocks, some having horizontal movements as much as eighteen miles.

The presidential address of Section V (Biological and Medical Sciences), entitled "The Causes of Hybrid Sterility and Incompatibility", was delivered by Prof. W. P. Thompson, of the University of Saskatchewan, and stressed particularly the time in the life-cycle at which the causes may operate.

A notable feature of the meeting was the group of papers on fish (and particularly on salmon). Prof. A. G. Huntsman described the habits of Atlantic salmon and discussed deaths due to high-water temperatures in the rivers of eastern Canada, while Prof. E. M. Walker presented the work of K. C. Fisher and P. E. Elson on temperature preference in Atlantic salmon and speckled trout. W. A. Clemens reported A. L. Pritchard's work on the age of coho and spring salmon of British Columbia and his own work on sockeye salmon in the same region. Attempts to explain the origin of kokanee (a variety of sockeye salmon) were made in a paper by W. E. Ricker, reported by R. E. Foerster. The close affinities of the Coregine fishes of Canada with Siberian species were dealt with by J. R. Dymond.

Desiccation in southern Ontario, as reflected in the decreasing mileage of streams, was the subject of a paper by A. F. Coventry, read by J. R. Dymond. This lead to an animated discussion as to the causes of desiccation.

Botanical papers included one by Prof. R. B. Thomson on the study of sporelings in the vascular cryptogams as a basis for the interpretation of seedling organization, another by H. B. Sifton on the development of the air spaces in the leaf of Labrador tea, and two by Prof. E. H. Moss on interxylary cork in Artemisia. Prof. G. W. Scarth summarized work on frost- and drought-resistance carried out with J. Levitt, B. Siminovitch and others and described the changes in the physical state of protoplasm associated with hardening.

James Miller discussed the parts played by the basal and prickle layers of the epidermis in regeneration and neoplasia, and M. L. Barr described the effect on the synapse of axon reactions in motor neurones. C. C. Macklin demonstrated that after over-inflation of the excised lung the internal septa and sheaths of the pulmonary blood vessels are similarly pneumatized. Dr. Benjamin Kropp brought forward much material to demonstrate that in spontaneous and therapeutic abortions structural abnormalities were present in the villus capillaries and villus epithelium. H. Wasteneys, B. F. Crocker and P. Hamilton reported that deuterium-labelled proteins are useful for the study of digestion in the dog. Madge Thurlow Macklin gave evidence that tumours in man have a genetic basis, and Lionel Penrose presented studies on the grandchildren of consanguineous unions. Dr. D. A. Scott discussed the structure of insulin crystals prepared from bison and human pancreases in comparison with those previously prepared from other sources. Dr. Leslie Young described his synthesis of aryl hydrogen sulphates *in vitro*.

Drs. Clark, Cleghorn, Ferguson and Fowler demonstrated that adrenal insufficiency results in a decrease in extracellular fluid and in plasma volume, that the percentage decrease of the former is less than the latter and that the decrease in plasma was not sufficient to account for circulatory collapse. Dr. Bram Rose presented evidence to show that in various types of shock there is a decrease in blood histamine. Dr. N. W. Roome advanced further evidence tending to dissociate the sympathetic nervous system from shock due to hæmorrhage. Prof. F. R. Miller demonstrated the local effects of eserine and acetylcholine on the electrogram of the cerebellar cortex. Dr. P. J. Maloney presented further evidences of the influence of bile salts on the flocculation of toxin. Prof. G. B. Reed described a semi-synthetic medium for the production of gas gangrene and tetanus toxins.

E. Horne Craigie described the area of distribution of the middle cerebral artery in birds and the form of the capillary bed of the central nervous system in Dermophis. J. McDunnough discussed some marine Coleophoridæ, and C. McLean Fraser described hydroids of the Pacific coast.

Other papers dealt with genetics of size (J. W. MacArthur) and the structure of homotypic and somatic chromosomes (L. C. Coleman).

Principal R. C. Wallace, of Queen's University, was elected president of the Society for the ensuing year.

CULTURE *IN VITRO* OF THE EXCISED EMBRYO OF AN OPHIUROID

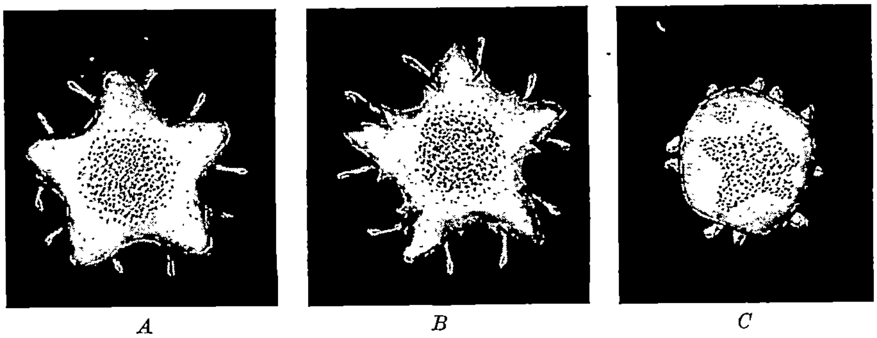
By H. Barraclough Fell,
Department of Zoology, University of Edinburgh

EXCISED embryos of the viviparous ophiuroid *Amphipholis squamata* have been successfully cultured *in vitro* by the method described below. It has been developed in the course of a study of the embryology of the species, and involves a modification of the watch-glass technique of Strangeways as described by Honor B. Fell and Robison[1]. As the culture medium Föyn's "Erdschreiber" has been used; this fluid has been employed previously by Dr. F. Gross for culturing the post-embryonic stages of fish, and various larvæ, and I am indebted to him for suggesting its use in the present instance.

The pregnant adult is anæsthetized by subjection to a solution of menthol in sea water. The embryos are excised from the bursæ and pipetted through several washings of sea water which has been sterilized. Each embryo is then placed in a small watch-glass (5 cm. diameter) and covered by 2–3 c.c. Erdschreiber medium, prepared as described by Gross[2] (p. 754). The watch-glass is set in a larger Petri dish, together with a sterile swab of wet cotton wool to keep the contained air humid, thus minimizing changes in the density of the culture medium through evaporation. The whole 'set-up' is surrounded by a bath of flowing tap water to keep the temperature reasonably constant. In practice, the medium has been renewed every fourth day, but a longer interval can be allowed. Aseptic technique must be used throughout, as the embryos are very susceptible to bacterial toxins. Embryos treated in this way have continued to grow and to differentiate in the usual way as if still within the bursæ of the parent, but with the advantage that the developmental changes can be observed in sequence.

The value of Erdschreiber as a medium for the culture *in vitro* of explanted embryos is demonstrated by the behaviour of controls cultured in the same way, but using as the culture medium sterile sea water which has been allowed to regain its normal oxygen content and *p*H value after sterilization. Freshly explanted embryos so treated appeared healthy and active until the sixth day, when it was observable that the yolk-mass, which is normally confined to the mesendoderm region, was assuming an irregular distribution through the tissues. The movements of the podia were feebler. On the seventh day the embryos had withdrawn the arm-buds and begun to assume a spherical form. Feeble movements of the podia still occurred, but they were shrunken and no longer capable of being used as organs of progression. By the eighth day one of the embryos had assumed the form of a ball of undifferentiated cells from which the vestiges of the podia protruded. In another embryo the cells of the disk had begun to grow out independently as in an ordinary tissue culture, and this condition persisted to the sixteenth day, when death occurred. On the other hand, embryos which had been placed in Erdschreiber at the beginning of the experiment had by the eighth day undergone considerable differentiation, and were moving about actively on the floors of the watch-glasses.

An embryo which had undergone retrograde development in sterile sea water was placed in Erdschreiber on the eighth day. The tissues, however, failed to redifferentiate, and after a period of unco-ordinated cell-division, death occurred.



A. Embryo when removed from the bursa. *B*. Same embryo after eight days culture in Erdschreiber, showing growth and differentiation of the arms. *C*. Retrograde development of another embryo after eight days in sterile sea water, having been at the same stage as *A* when removed from the bursa.

The development of the embryo will be described later elsewhere. It may, however, be stated here that a comparison of the results of culturing embryos in Erdschreiber and in sterile sea water shows that the embryo is unable to develop on its own yolk material alone, requiring the addition of other substances to the medium. These substances, whatever they may be, are contained in Erdschreiber (an aqueous extract of earth by autoclaving, plus sodium nitrate and disodium hydrogen phosphate). Therefore, we are justified in concluding that the wall of the bursa secretes a nutrient substance which is directly absorbed by the embryo within. This deduction is in agreement with the fact that the bursal wall contains numerous sinuses. In the absence of the necessary substance or substances, the embryo remains for a while apparently healthy, and then undergoes a retrograde development, resulting finally in an amorphous mass of cells. The fact is interesting in that it indicates the closeness of the interrelationship that can exist between parent and embryo in the echinoderms.

STEREOPHONIC RECORDINGS OF ENHANCED MUSIC

DEMONSTRATIONS of the stereophonic reproduction of music and speech were given at the Carnegie Hall in New York City on April 9 and 10. This was the culmination of a long series of researches by Bell Telephone Laboratories. The first step in this achievement was demonstrated in 1933, when a symphony concert produced in Philadelphia was transmitted over telephone wires to Washington and there reproduced stereophonically and with enhancement before the National Academy of Sciences. Subsequent researches by Dr. H. Fletcher and his colleagues at the Bell Laboratories have supplied the equipment and technique for recording such a production on film.

With the co-operation of Leopold Stokowski and the Philadelphia Orchestra, the Tabernacle Choir and organists in Salt Lake City, and of Paul Robeson and other artists, their music and drama was recorded both in Philadelphia and in Salt Lake City. At a later audition, the director or artist was able to vary the recorded volume and to change the tonal colour of the music to suit his taste. He could soften it to the faintest pianissimo or amplify it to a volume ten times that of any orchestra without altering its tone quality, or he could augment or reduce the high or low pitches independently. While he was thus enhancing the music which he himself had directed, his interpretation was being re-recorded on film as a permanent record.

Selections for reproduction, chosen to demonstrate the full capabilities of this system, were given. From the choral numbers, vocal solos, organ, drums and grand opera reproduced at Carnegie Hall, the audience gained an idea of the versatility of the stereophonic system. A stirring climax for the programme was provided by the closing scene of the "Götterdämmerung". Dr. Stokowski took full advantage of the tenfold increase of sound over that of the largest orchestra, and effectively used the individual control to make the soloists' voice clearly heard above the orchestra. Dr. Stokowski has shown a full grasp of the possibilities of the new system.

In the *New York World Telegraph* of April 10, L. Biancolli describes a new effect demonstrated at Carnegie Hall. When the light went out all that one saw was a gossamer veil hung across the stage, with a soft red glow playing on it. Then a flute sounded thinly from the distance; a crowd bellowed thunderously; horses galloped by; thunder rumbled; a man talked as he walked from one end of the stage to the other. Then the whole width, breadth and depth of a symphony orchestra went into action. It sounded real, spread out in space. But it all came from a set of sound boxes and horns each functioning separately and in unison. "Dogged research in electricity, acoustics, dynamics had shown one more miracle—spread-out sound coming straight from the source, with no hint of crowding. Drums were at one end, flutes at another and in between other instruments were heard clearly across the stage. There was no blurring, no congestion. Pianissimi were the merest hush and fortissimi had the impact of a cannonade. The trick of giving orchestral music 'position' in recordings and weaving in nuances between nuances is now a perfected fact."

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

CIVIL ENGINEERING ASSISTANT—The Waterworks Engineer, Town Hall, Wakefield (August 8).

TEACHER OF MECHANICAL ENGINEERING at the Smethwick Municipal College—The Chief Education Officer, 215 High Street, Smethwick.

THE CHALLENGE OF SCIENCE

THE widespread utilization of science in both offensive and defensive warfare has brought into fresh prominence the old question whether science is a curse or a blessing. Such a discussion cannot even in these times be dismissed as purely academic. Behind many of the problems with which we are concerned in the war effort, such as food production and factory welfare, lies the major question confronting Western society to-day, that of harnessing science to human welfare. The misuse of discoveries and inventions must not be allowed to obscure their beneficent effects. As Prof. J. C. Philip pointed out in his recent presidential address to the Society of Chemical Industry, inventions, materials and machines are not in themselves good or evil; the character of the part they play in the human drama is determined by man himself, and the tragedy is due to human weakness and failure.

On this, recent events in France may well make a vivid commentary. There is no need to subscribe to the view that widespread appreciation of science and better systematizing of human knowledge offer a panacea for the ills and maladjustments of humanity. But abandonment of extravagant claims on behalf of science does not affect the tremendous opportunities of using it as a tool for the benefit of humanity. The tragedy lies in that men have looked backward instead of forward. Realizing that neither physical science nor industry are ends in themselves and that material things cannot be allowed to dominate human life, they have sometimes thought they should be ignored—that because ends are more than means, means are of no account.

Scientific workers may well be grateful for Viscount Samuel's words on this subject in his Messel Lecture, "Science and Civilization", before the Society of Chemical Industry on July 9. Applied science, he asserts, is worth while not only for what its achievements are in themselves but also for the sake of the ends they make possible. To blame science for the present war is unreasonable; as though there had been no warfare before the age of science. Even if the humane nations were to restrict or abolish industrial science, as an accessory to the crimes of war, we may be sure the inhuman nations would not. We cannot leave Justice with only her ancient sword to face Injustice armed with machine-gun and grenades.

A wider view, therefore, urges Viscount Samuel, will dispose of the hasty judgment that the world would be the better if it sought to discard the scientific altogether, and went back to the primitive. On the contrary, while recognizing that it should seek no monopoly in our activities, or even predominance, science, vindicated in its purposes, may rightly ask from society as a whole the conditions that will best develop its efficiency and ensure its success in tasks that are beneficent and indispensable.

A full realization of the possibilities which science has put into our hands, not merely in regard to production and leisure, but also through the lengthening of human life by the control of disease, the removal of the environmental causes in early life of many of the physical, mental and spiritual defects from which we suffer, as revealed by the new sciences of nutrition, eugenics and psychology, and the development of man's latent capacities of greatness and goodness, might well, as Sir John Orr has urged, prove a decisive factor in the development of some new system of world order. What is essential is that men should face the development of the new order with the same courage, the same confidence and willingness to venture as they are displaying in the prosecution of the War.

A timely and valuable contribution to the discussion has been provided by Prof. H. Levy in a recent pamphlet.* Prof. Levy takes the view that lack of courage has been shown by many educated men and women who have realized the creative power which science has placed in their hands and yet are conscious of the havoc and destruction to which that power has been turned. The turning to mysticism is a turning away from a contribution to the reasoned understanding of the forces of Nature. It is failure at a critical moment in world history to concentrate the mind and brain-power of men on vital problems the solution of which is so urgent that every ounce of thought should be directed to their analysis. It is akin to the defeatism and moral paralysis which have contributed so largely to the overthrow of France.

This, as Prof. Levy points out, is treachery indeed to science, and deals a staggering blow to humanity. When men need strength and self-reliance they are offered insecurity ; when men require to face realities they are offered illusions, presented in the terms of those branches of science most remote from the common understanding, trading on popular ignorance and exploiting popular fear and interest in the mysterious. It is this confusion, for which some men of science must share the responsibility, that has hindered the forward view, the resolute shaping of policy and the fruitful impact of science on philosophy itself.

Scientific laws have a twofold aspect which is apt to be overlooked at this time of confusion. There are laws of order and laws of accident as well, and even accidents taken in the mass can be studied systematically. If philosophy is to base itself on the fullest knowledge, it must begin with the established findings of science. It must see the historical evolution of men and the tentative nature of their knowledge. It must adopt the experimental method with regard to the discovery of new generalizations, and learn how to avoid the dangers involved in false formulations of its problems.

Prof. Levy rightly emphasizes this philosophical aspect, for here can be found the corrective to the narrow perspective which is one of the dangers to be guarded against in a struggle like the present, with its tremendous demands upon our energy and thought. It is not the least of the merits of his pamphlet that it assists us to view the struggle itself in a wider and truer perspective which may well fortify our resolution and inspire us with fresh devotion.

The coming of this catastrophe, Prof. Levy suggests, is, from the point of view of the utilization of science, the climax to a process of human and scientific frustration that had rapidly been making itself apparent for almost a generation, just when the most striking advances were being made in almost all branches of physics, chemistry and biology.

We have now to recognize that concentration on war-time problems has shut down almost completely what might be called the cultural side, and the more barbaric side has become dominant. If this position reminds us that science itself is an aspect of social change, and must bend to the more compelling social demand, and that the direction of scientific advance must align itself with needs other than those of the internal logic of the scientific subject itself, there are at least elements of hope in the situation.

It is no matter for regret that the false idea that science is an independent discipline of its own, owing nothing and giving nothing to society, should be exploded. Moreover, some of the war-time problems have emphasized the urgent need for scientific knowledge and further research at precisely those points in the front of science where we had already become aware that the uneven advance was handicapping scientific as well as social development. The survey of man-power at present being conducted by Sir William Beveridge will unquestionably be assisted by the studies of the location of industry already conducted by P E P (Political and Economic Planning) and by the report of the Royal Commission on the Distribution of the Industrial Population The requirements of civil defence and now of defence against invasion have underlined the arguments in such reports in favour of co-ordination and regionalism, and many important problems in local government, decentralization and the like, have been raised, the solution of which on rational lines to meet war emergencies may well clear the way for further advance later.

Besides this, evacuation questions have emphasized the need for more sociological research and may well give an impetus to many much needed investigations. The scientific study of th question of food supply and production is now being undertaken on a much more adequate basis, and the elaboration of policy and measures designed to ensure at least an adequate 'iron ration' for the whole population may not only lead to the more scientific utilization of our resources but also to the further advance of agricultural and horticultural science, and to a frontal attack on the problems of malnutrition and under-nourishment. Other problems or needs of war-time have strengthened forces making for a more intensive attack on problems of disease or other matters of public health.

---

*Science—Curse or Blessing? By Prof. H. Levy. (Thinkers Forum, 4.) Pp. 48. (London: Watts and Co., Ltd., 1940.) 6d. net.

Preoccupation with the effort required to prosecute the War should not therefore lead us to overlook the fact that in the profound changes involved new opportunities and possibilities are opening up before us. Vested interests or embedded prejudices that have long blocked progress are being compelled to yield before national exigencies, and we should not allow them again to hold up social or scientific advance when the War has been won. The period of scientific frustration through which we have passed is evidence of the inability of the old system to avail itself constructively of the new knowledge to usher in a new level of social life. Repression of progressive ideas, whether in Fascist or in Democratic countries, is treason to science no less than to civilization and the abiding values of man's cultural and moral heritage.

This is indeed one of our gravest dangers—that our condemnation of War itself or concentration on immediate war tasks should lead us into the company of those who cannot believe that Europe is in the throes of the birth-pangs of a new society in which they are called to play an entirely new part. The chances which the War itself offers us of ultimately building a new and better world order will not be used by those whose minds are set in old-established grooves or are afraid to face new situations and use new methods.

Whether science is a curse or a blessing depends fundamentally on whether we are prepared to meet the challenge which it throws down to us in economic and in moral affairs. The individual basis for conduct in a modern complex society is inadequate. We have to face the reorganization and reorientation of industry, of society, and of ethics itself, on a social as well as an individual basis, if our democratic institutions are to stand the strain which is thrown on them now that science and its technical applications, by binding groups together as entities, have made them socially and economically interdependent.

The issue depends largely on whether we bring to that task a width of vision and openness of mind, a firmness of purpose and a courage and comradeship commensurate with those demanded of us in this present hour of trial. It also depends on whether even now we are prepared to undertake the preliminary thought and investigation, the linking up of the war effort with the task of reconstruction, so that the opportunity to rebuild when it comes to us is not missed for lack of vision or preparation as it was two decades ago.

A NEW TRANSLATION OF THE TELL EL-AMARNA LETTERS

The Tell el-Amarna Tablets
Edited by Prof. Samuel A. B. Mercer, with the assistance of Prof. Frank Hudson Hallock in the final revision of the Manuscript. Luxor edition. 2 vols. Vol. 1. Pp. xxiv+442. Vol. 2. Pp. iv+443–910. (Toronto: The Macmillan Company of Canada, Ltd., 1939). 84*s*. net.

IT is fifty-three years since the famous collection of cuneiform tablets known as the Tell el-Amarna Letters was discovered on the site of the ancient capital of Amenophis IV, better known as Akhnaton, the 'heretic' Pharaoh. Twenty-eight years after the discovery, a careful edition of the text, with translation, notes and glossary, was produced in German by Knudtzon, with the collaboration of Weber and Ebeling. In the interval an edition, of a somewhat provisional nature, had been published by Hugo Winckler, and translated into English by Mr. J. M. P. Metcalf, in 1896. But, until the appearance of the present edition from the hand of Prof. Mercer, English scholarship has produced no independent edition of these most important documents.

This is not to say that the Tell el-Amarna Letters have been ignored by English scholars, as may be seen from such studies as the late Prof. Burney's Schweich lectures on Israelite settlement in Canaan, and Prof. S. A. Cook's admirable chapter on Syria and Palestine in the light of external evidence, in the second volume of the "Cambridge Ancient History". But Prof. Burney's book was written in 1917, and volume 2 of the "Cambridge Ancient History" appeared in 1924, so that a quarter of a century has elapsed since the last authoritative discussion of the significance of these documents from the pen of any English scholar.

Meanwhile, great advances have been made in our knowledge of the history and civilization of the ancient Near East. The archives of Boghazköi have been unsealed at last, throwing a flood of new light on the history of the great Hittite Empire during the first half of the second millennium B.C. The publication of the texts from Nuzi and Kirkuk, the discoveries at Ras Shamra, the site of the ancient city of Ugarit, mentioned in the Tell el-Amarna correspondence, M. Parrot's excavations at Mari, Sir Leonard Woolley's results from the excavation of Atchana, and Mr. Mallowan's recent work at Brak, have all combined to illuminate many problems raised since the appearance of the Tell el-Amarna Letters.

Hence it was full time to attempt an edition of the Letters for English-speaking students which should apply the gains of half a century to the elucidation of the many problems still awaiting solution.

In his preface, Prof. Mercer assures us that "wherever new light has been thrown upon unsolved problems, it has been recorded in full", and offers his edition of the Letters "to all students of the Tell el-Amarna tablets, and of the general field which they represent, as an attempt at the last word to date on the subject", adding the qualification that it is merely tentative, "a stepping-stone to a future and better edition whenever new material and new knowledge shall make that desirable".

The work before us consists of 815 pages containing the text and an English translation on opposite pages, with very brief footnotes. We have then 34 pages of Excursus, consisting of nine short essays dealing with various subjects, two of the essays being from the pen of Prof. Hallock. The book is completed by a glossary of 30 pages and indexes of personal and geographical names, and a map of the Tell el-Amarna world. The type and format are all that could be desired.

It must be said at the outset that many English students will be grateful for the boon of an English translation. But from the scholar's point of view (and Prof. Mercer assumes that those who use his edition are already familiar with Knudtzon) the question is bound to be asked whether Prof. Mercer's translation is an improvement on its predecessor in the many passages where the German pioneer version has been recognized to be at fault. A careful comparison shows that Pro Mercer has followed Knudtzon very closely, eve in his mistakes, and that there are several mis translations which arise from a misunderstandin of the German. But a more seriously misleadin feature of the present translation is the abandonment of all the diacritical marks whereby Knudtzo distinguished between the various degrees o probability in his version, so that we have no offered to us without any indication of uncertaint translations which Knudtzon offered only a doubtful conjectures. Hence the student canno safely use Prof. Mercer's translation without havin Knudtzon continually before him.

Students of the philological problems raised b the Letters will turn to the Excursus section o volume 2 in the hope of learning what advance have been made in this field during the last half-century. They will not even find a page devoted to the linguistic peculiarities of the Letters, and it is stated that the language of these documents is Akkadian, although it is now recognized that not more than twenty letters out of the whole collection can be correctly characterized as Akkadian. Indeed, it may safely be said that the language of the greater part of the letters bears the same relation to Akkadian that the language of the books of Esther or Ecclesiastes bears to classical Hebrew.

Another field in which enormous advances have been made is that of Hittite studies. Here, again, the student who consults Excursus V in the hope of finding the last word on the Hittites and their importance in the political activities of the first half of the second millennium B.C. will be disappointed, for the essay represents the state of knowledge about the Hittites which had been reached a quarter of a century ago, and has not even been brought into line with some of the author's footnotes and references to modern literature on the subject, or with the two excellent essays by Prof. Hallock on the Hurrians and the much-debated problem of the Habiru. One has only to compare the map of the Tell el-Amarna world at the end of volume 2 with the map of the same period given in Goetze's "Hethiter, Churriter und Assyrer" (1936) to appreciate the time-lag in knowledge there revealed.

It is with great regret that the judgment must be recorded that a book so much needed, and on which so much devoted labour has been expended, to say nothing of the gallant and generous support of those friends of learning to whom the book owes its publication, fails to meet the tests which modern scholarship will apply to it. None the less, the labours of the author and the loyalty of his friends call for some expression of admiration and gratitude.

S. H. HOOKE.

Historian and Scientist

An Essay on the Nature of History and the Social Sciences. By Gaetano Salvemini. Pp. ix+203. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1939.) 9*s*. 6*d*. net.

PROF. SALVEMINI has been very well known in Great Britain for more than ten years. He was arrested as an opponent of the Fascist system in 1925, and in the next year was dismissed from his professorship in Florence and had to leave Italy, all his property being confiscated. He has spent the greater part of the time since in Great Britain, made many friends and inspired many with a mind both broad in its grasp and subtle in its distinctions. Latterly, he has been lecturing in the United States, and the book before us consists of interesting reflections on the relations of history and physical science by one who pretends to no special knowledge of the latter but sees clearly that there is an intimate connexion between the two. He rejects early in the book the claim put forward by Cicero that history is not only the *lumen veritatis*, the light of truth, but also the *magistra vitæ*, the teacher of life. This claim cannot be admitted, because the historian and the social scientist have to solve problems of facts and laws like the physicist but not pronounce upon their value. Ethics stands on a pedestal above, and Prof. Salvemini would therefore separate himself from Lord Acton, to whom the moral goodness or badness of his subjects was the supreme object of study.

But if Salvemini limits the scope of history on this side, he widens it immeasurably on another. Directly or indirectly, all historical research aims at solving the basic problem of knowing how the present situation has come to be as it is. This aim clearly covers the state of the physical as of the human world. The whole universe as known to us has been developing from some earlier state, going back to incalculable or infinite ages; the methods used in discovering how it has changed must be similar, though not identical.

Prof. Salvemini is explicit on this point. He tells us that the laws of social life—which includes history—cannot be determined except by the method followed during the past three centuries by the sciences of the physical world—that is, by examining the greatest possible number of facts. The method is the same but the material is different. In each case the facts begin to acquire significance when they are grouped in a system of cause and effect. So far, history and science are alike. They both aim at constructing a system by which the sequence, as we know it, followed by a certain law from what has gone before.

Unfortunately, the remains of the past have very rarely come down to us in a perfect or even reliable condition. This makes the great gulf between the results of the scientist and those of the historian. While the biologist is studying an organ or the chemist analysing a substance or the astronomer observing a star, the historian has to restore the remains which he examines to their original form and detect frequent forgeries and the variations of the different observers who may be faithfully attempting to record what is going on around them. We know in all ages—even in our own of exact wireless reproduction—how widely the impression will differ of any given event which is being recorded. There must be an absolute truth, but it would seem to be beyond the reach of the human mind as it is now constituted to attain it. To take the latest different version of the same event—how much agreement should we find between that of the secretary of Mr. Chamberlain at Munich and that inspired by Herr Hitler or his companions?

We come then to three main results from Prof. Salvemini's survey:

(1) The universe contains an infinite number of objects and events, constantly changing; the neutron is one and the brain-cell another. All may be part of a universal life so far as we are aware. All are material for the study of the scientist and the historian. They are alike in their method of studying the facts, comparing them and attempting to draw some line of filiation from one state or moment to another. This was the method of science developed some three centuries ago and Salvemini would have it applied both to what we call 'organic' and 'inorganic'. So far we must class him with the positive school of thinkers.

(2) The immense difference arises when we consider the simplicity and apparent immobility of the inanimate and the incessant and baffling movement of the living. We do not take this as a final fact, but note it as the present supreme difficulty between the work of the physical scientist and the historian or student of human affairs. For the moment it makes their results incomparably different. We can direct our Blenheim bombers with the utmost accuracy to

the desired spot; we have but the most generalized idea of what is meant when there is talk of an attack on a certain country, nor can we predict the result if such an attack took place.

(3) The parallel inquiries of the scientist and the historian or sociologist are constantly advancing and constantly finding points of contact between the non-living and the living. We are often, it would seem, on the threshold of discovering the point at which the inanimate became the living. It has not yet been found, but an infinity of time remains to breach the gulf and achieve the unity which the word 'universe' implies.

F. S. MARVIN.

HAMILTON'S DYNAMICS

The Mathematical Papers of Sir William Rowan Hamilton

Vol. 2: Dynamics. Edited for the Royal Irish Academy by Prof. A. W. Conway and Dr. A. J. McConnell. (Cunningham Memoir No. 14.) Pp. xvi+656. (Cambridge: At the University Press, 1940.) 70*s.* net.

THIS is the second of the projected four volumes of the mathematical papers of Sir William Rowan Hamilton. The first volume, published in 1931, contained papers on geometrical optics, and the present volume is mainly devoted to dynamics, but includes also some papers on Hamilton's calculus of principal relations, which, as the editors state in the preface, is a natural and obvious extension of his method of the principal function. These volumes differ from most collections of the papers of a mathematician in the very large proportion of hitherto unpublished matter which they contain. Thus in the volume under review we find that the papers here reprinted comprise the two important papers on "General Method in Dynamics" from the *Transactions of the Royal Society*, of 1834–35, and in addition only thirty-five pages of British Association Reports on Hamilton's work and brief notes on such subjects as the dynamics of light, the composition of forces and the hodograph, while the matter now printed for the first time, a hundred years after it was written, runs to more than 460 pages. With a few minor exceptions the whole of the work was written between 1833 and 1839, the characteristic function having first been introduced in the paper on "Theory of Systems of Rays" published in 1827. The editors have told us that the Library at Trinity College, Dublin, contains more than two hundred volumes of Hamilton's notebooks in addition to unbound manuscripts. The selection of what is most suitable for publication and the editing of the papers can be no easy task, and we can only express our admiration for the skill with which the great work is being accomplished.

As in volume 1, the editors remind us that "Hamilton arrived at his conclusions by heavy and laborious preliminary work and by the working of many examples often reached the general results gradually through the particular. When he finally published his results, they appeared in very compact and condensed form, which made his published papers somewhat difficult reading and gave little indication of the labour by which he arrived at the end of his journey". This fact is illustrated by the opening paper of this volume, entitled "Problem of Three Bodies by My Characteristic Function", dated 1833, not hitherto published and preceding by a year the publication of the first of the two papers on "General Method in Dynamics" which follow in this book. The paper contains some interesting results, such as the characteristic function for two bodies, and we see how, by considering the special case of elliptic motion, Hamilton discovered the formula $\delta V/\delta h = t$. But to an average mathematical reader, who would welcome some light on the two following papers, this formidable article of 100 quarto pages with its 1,289 numbered equations may appear a rather forbidding proposition.

To revert to the general arrangement of the book, it consists of three parts. Part 1, "Dynamics of Material Bodies", is concerned almost entirely with the characteristic and principal functions and their applications, and contains a lengthy correspondence with J. W. Lubbock on the application of Hamilton's methods to lunar theory. It also shows us Hamilton inventing the hodograph, though in this Möbius had anticipated him, and Hamilton inventing a proof that the resultant of two rectangular forces is directed along the diagonal of the rectangle.

Part 2, "Calculus of Principal Relations". With the exception of a brief summary in the form of a report to the British Association (1836), this part of the book consists entirely of work not previously published. It is an extension of the method of applying the principal function by means of calculus of variations to the solution of total and partial differential equations. The manuscripts are all of date 1836. It was Hamilton's intention to write a book on the subject, and the four papers now published were written with this aim in view; but like the projected text-book, which was to show students how to apply the characteristic function to problems in geometrical optics, it was not completed.

Part 3, "Dynamics of Light". This part consists of long papers on the propagation of light in crystals, researches respecting vibration connected with the theory of light, and propagation of motion in elastic medium – discrete molecules, all hitherto unpublished, some short notes on researches, and a correspondence on the dynamics of light with Prof. Powell and Sir John Herschel, all of date 1835–39. In one of these papers we find the theory of group-velocity as distinct from phase-velocity, though this theory has often been attributed to Stokes, who set a question on the subject in the Smith's Prize Examination forty years later.

These papers of Hamilton are prefaced by a useful introduction and followed by an editors' appendix, which contains a number of valuable explanatory notes elucidating difficulties in the text and giving references to modern developments. Among these is a short article which quotes Jacobi's criticism of Hamilton's method and explains a method of the editors of obtaining the Hamiltonian form of the principal function S and characteristic function V from Jacobi's complete integral, with several applications.

The first volume was edited by Prof. A. W. Conway and Prof. J. L. Synge. In producing the second volume Prof. Conway has had Prof. A. J. McConnell as his associate, and they are to be congratulated on the production of this further monument to one of the greatest of Irishmen.

A. S. RAMSEY.

THE INTERIOR OF THE EARTH

Physics of the Earth
7: Internal Constitution of the Earth. Edited by Prof. Beno Gutenberg. Contributors: L. H. Adams, Reginald A. Daly, B. Gutenberg, Harold Jeffreys, Walter D. Lambert, James B. Macelwane, *S. J.*, C. F. Richter, C. E. van Orstrand, H. S. Washington. Pp. x+413. (New York and London: McGraw-Hill Book Co., Inc., 1939.) 30*s*.

THE nature of the earth's interior has been a subject of speculation for thousands of years. Ancient philosophers, from the Babylonians onwards, firmly held the belief that the depths were largely occupied by water. Even in the volcanic regions of the Mediterranean, where the subterranean world was naturally associated with ideas of internal fire, this belief was not excluded. Moreover, the winds of the Aeolian Isles were regarded as draughts generated from immense air-filled cavities by the action of the volcanic hearths. These traditional views persisted unchallenged until well into the seventeenth century. In 1695, for example, we find them repeated with characteristic exuberance by John Woodward. But already less fanciful notions were beginning to be formulated. Leibniz in 1680 had clearly expressed the idea of a crystalline crust resting on a molten interior; and a century later (1788) Benjamin Franklin asks: "Can we easily conceive how the strata of the earth could have been so deranged if it had not been a mere shell supported by a heavier fluid?" However, before another century had elapsed, Hopkins and Kelvin had shown that a fluid interior was inconsistent with the phenomena of precession and the tides, and geologists were left to puzzle over Franklin's problem as best they could. With the present century has come the realization that 'non-fluid' or 'solid' does not necessarily imply the crystalline state; vitreous material would fulfil still better the conditions imposed on speculation by the earth's behaviour.

A growing band of geophysicists is now actively engaged in the attempt to solve the dark problems of the earth's interior. The volume under review records progress to date in a series of chapters written by some of the leaders in this field of research. The work is a collective one and certain differences of opinion and interpretation still remain among some of the collaborators. This is not unnatural, since the various lines of evidence do not always lead to unique conclusions. The hypothetical identification of sub-crustal material with dunite (olivine-rock) is a case in point. Here the evidence is that the sub-crustal velocities of earthquake waves correspond roughly with those calculated from the density and elastic constants of dunite under high pressure. But to identify the material with dunite is probably just as wrong as to assume that a substance with the refractive index of water is necessarily water. In the latter case the substance might be cryolite. Geologists will notice with relief that in the present volume the 'dunite' hypothesis is no longer specially favoured.

In his editorial introduction Gutenberg is careful to point out one fertile source of confusion: the fact that the transition from solid to fluid need not be connected, as it has been popularly supposed to be, with the transition from crystalline to non-crystalline. Non-crystalline material, even above the melting point, may be a vitreous solid with high rigidity and viscosity. The problem of the distribution of crystalline and vitreous material in the solid part of the earth is not yet wholly solved.

Jeffreys provides an admirably lucid chapter on the origin of the solar system. He concludes with a succinct statement of the contribution of cosmogony to geophysics: "The earth was once liquid. In this state its free iron and materials soluble in it settled to the center, leaving the silicate shell outside. Since then the shell has become solid, but the core remains liquid to this day."

Daly reviews the approach from geology. He shows that the phenomena of isostasy and the lateral shortening of orogenic belts imply a weak asthenosphere. From the fact that enormous masses of basalt have flooded the surface he infers the existence of a world-circling sub-crustal layer of basaltic composition which, he thinks, at least in the lower part, is in the vitreous state. The trouble about the latter conception is the attendant probability that basaltic eruptions, once started, would fail to stop until the whole of the vitreous part had been expelled. This difficulty would not arise if the vitreous material were of ultrabasic composition. Overlying crystalline basaltic material would then be eruptible only when and where it became locally liquefied, as it might be by the action of sub-crustal convection currents. Daly considers that in Pre-Cambrian times the lithosphere was specially thin and that it was then invaded by magmas on a scale never since equalled; he goes on to correlate these conditions with the probability that the radioactivity of the rocks was then considerably greater than at present. This raises many interesting problems, but they can only be discussed speculatively while we remain in doubt as to the origin of the continents and the reasons for their lateral limitations. Beyond a vague suggestion that the moon may be in some way connected with the absence of continental layers from the sub-Pacific crust, this fundamental question is barely referred to in the present volume.

Besides the introduction and a final summing-up, Gutenberg contributes five other chapters, dealing with the cooling of the earth, forces in the earth's crust, hypotheses on the development of the crust, and the elastic constants, viscosity, strength and internal friction in the interior; in collaboration with Richter he also reviews the evidence from deep-focus earthquakes and summarizes our knowledge of the crustal structure of continents and ocean floors. As there is still no general agreement as to whether or not more heat is produced inside the earth than escapes from it, it is not possible to estimate the importance of thermal contraction in the tectonic history of the earth. Gutenberg thinks that sub-crustal currents, controlled mainly by radio-thermal processes, seem to play the most important part. He refers to seismic evidence suggesting that the transition from crystalline crust to vitreous substratum takes place at a depth of about 60–80 km. The viscosity of the substratum is not too high to prevent convection currents. Those interested in the recent development of the convection current hypothesis should refer to an illuminating paper by Griggs (*Amer. J. Sci.*, Sept. 1939), which appeared too late to be noticed in the present volume.

The elastic properties of crustal materials are reviewed by Adams and the seismic evidence on earth structures by Macelwane. Lambert writes on density, gravity, pressure and ellipticity in the interior. These chapters contain valuable tables of data not easily accessible elsewhere, as indeed does the book as a whole. The observed temperatures in the earth's crust are recorded and discussed by van Orstrand. Readers who are specially interested in this topic will appreciate two relevant papers on heat flow in Great Britain and South Africa that have recently appeared (*Proc. Roy. Soc.*, A, pp. 428–450 and 474–502; 1939). Geochemical aspects of the earth's constitution are discussed by Washington in a posthumous chapter prepared several years ago, but recently revised by Adams. It contains an interesting account of meteorites and tectites and also a brief section on terrestrial magnetism. The absence of a chapter dealing more systematically with the latter subject is probably to be ascribed to the fact that Vol. 8 of this series on the "Physics of the Earth" is devoted to terrestrial magnetism and electricity (see NATURE, Jan. 13, 1940, p. 47).

Finally, mention should be made of the very full bibliographies. Each chapter—except the final summary—has its own, and altogether there are 852 references, more than a quarter of which are to seismic evidence and its application to the exploration of crust, substratum and core. Prof. Gutenberg and his committee are to be congratulated on the production of a well-written, authoritative and most welcome book which will be highly and deservedly appreciated by a very wide circle of readers in many branches of science.

ARTHUR HOLMES.

CONSERVATION AS A FOUNDATION OF PERMANENT PEACE*

By The Hon. Gifford Pinchot,

Former Governor of the State of Pennsylvania

THIRTY-TWO years ago there was held in Washington a Conference which was the first of its kind. It was the first not only in America but also in the world. It was also the first conference in the history of this country of the Governors of all the States and Territories with the President of the United States. Since it included also the Congress, the Cabinet, the Supreme Court, scientific experts, representatives of national associations, and outstanding citizens, it was one of the most distinguished gatherings ever brought together in the United States.

But no one of these was the essential reason for its epoch-making importance. The reason why the meeting of the Governors with President Theodore Roosevelt in the White House in May, 1908, may well be regarded by future historians as a turning point in human history, the reason why it exerted and continues to exert a vital influence on the United States, on the other nations of the Americas, and on the nations of the whole world, is this: it was called to introduce, and it did introduce, to mankind the newly formulated policy of the conservation of natural resources.

Even at that time the profound significance of conservation was beginning to make itself felt. In announcing his intention of calling the Conference, the President said: "The conservation of natural resources is the fundamental problem. Unless we solve that problem it will avail us little to solve all others. . . . It [the Conference] ought to be among the most important gatherings in our history, for none has had a more vital question to consider."

This Conference set forth in impressive fashion, and it was the first national meeting in any country to set forth, the idea that the protection, preservation, and wise use of the natural resources of the earth is not a series of separate and independent tasks but one single problem. As the President said: "The various uses of our natural resources are so closely connected that they should be co-ordinated, and should be treated as parts of one coherent plan."

The Conference asserted that the conservation of natural resources is the one most fundamentally important problem of all. It drove home the basic truth that the planned and orderly development of the earth and all it contains is absolutely indispensable to the permanent prosperity of the human race. It spread far and wide the new proposition that the purpose of the conservation of natural resources is the greatest good of the greatest number for the longest time. It taught the people of the United States, and other peoples, the new meaning of the word conservation, which in its present application to natural resources was then generally unknown.

By defining, describing, and making known the new word and the new policy, by endowing it with the approval and support of the leaders of all the States, of the great industries, and of the nation itself, the Governor's Conference put conservation in a firm place in the knowledge and the thoughts of the people. From that moment conservation became an inseparable part of the national policy of the United States.

It is worth mention that this brilliant example of national foresight occurred not in a time of scarcity, not in a depression, but in a time of general abundance and well-being. The unanimous declaration of the Governors ended with this discerning admonition: "Let us conserve the foundations of our prosperity."

It may be difficult to-day, when conservation is accepted almost as widely as the Ten Commandments, to realize that only a generation ago there was no such thing as a conservation policy. The very word conservation, as we use it to-day, had no existence.

The conception which we know as conservation originated and was formulated in the United States Forest Service in the early winter of 1907. Conservation grew out of forestry. Thus, conservation was born without a name. But it had to be given a name before it could be introduced to the people.

After discussion among perhaps half a dozen men, the name conservation was tentatively decided on. Thereupon it was submitted to and approved by Theodore Roosevelt, and the infant was christened accordingly. We know the growing youngster, thirty-three years old but growing still, by that same name to-day. The hold conservation has gained in these thirty-three years upon the civilized peoples of the world is little less than amazing. To-day the soundness of the conservation policy is everywhere accepted as a matter of course.

---

*Substance of a paper read on May 11 before the Eighth American Scientific Congress at Washington.

The Conference of Governors recommended and was followed by the appointment of conservation commissions by a majority of the States, and of the National Conservation Commission, which latter in January of 1909 submitted to the President the first national inventory of natural resources ever made. In February of the same year the North American Conservation Conference, the first international conference to consider the policy of conservation, met in Washington at the invitation of President Theodore Roosevelt.

In his address at the opening of the Conference in the White House the President made this highly significant statement:

"... In international relations the great feature of the growth of the last century has been the gradual recognition of the fact that instead of its being normally to the interest of one nation to see another depressed, it is normally to the interest of each nation to see the others elevated. . . . I believe that the movement that you this day initiate is one of the utmost importance to this hemisphere and may become of the utmost importance to the world at large."

The North American Conservation Conference declared that the movement for the conservation of natural resources on the continent of North America "is of such a nature and of such general importance that it should become world-wide in its scope". Therefore it suggested to the President "that all nations should be invited to join together in conference on the subject of world resources and their inventory, conservation, and wise utilization".

What the Conference thus recommended was, however, already under way. The President had foreseen that the North American Conference would be the precursor of a world conference. Accordingly, to quote Elihu Root, then Secretary of State: "By an aide-memoire in January last [1909], the principal governments were informally sounded to ascertain whether they would look with favour upon an invitation to send delegates to such a conference. The responses have so far been uniformly favourable, and the conference of Washington has suggested to the President that a similar general conference be called by him. The President feels, therefore, that it is timely to initiate the suggested world conference for the conservation of natural resources, by a formal invitation."

With the concurrence of the Netherlands, invitations were sent to fifty-eight nations to meet at the Peace Palace in The Hague in September, 1909. Thirty of the nations, including Great Britain, France, Germany, Canada, and Mexico, had already accepted when President Taft, who succeeded Theodore Roosevelt on March 4, 1909, killed the plan.

Two attempts have been made to revive it. At the end of the War of 1914-18, President Wilson, at the suggestion of Colonel House, took steps toward securing world-wide co-operation in the conservation and distribution of natural resources. Unfortunately nothing came of it.

During President Hoover's administration a group of nearly two hundred leading citizens from all parts of the United States urged him in a public petition to take action along the same general line. Again nothing came of it.

But these checks notwithstanding, the conservation problem remains the fundamental human problem. Without natural resources, no human life is possible. Without abundant natural resources civilized life can neither be developed nor maintained. To the human race, land is the basic natural resource. The demand for new territory, made by one nation against another, is a demand for additional natural resources; and it is not necessary to point out how many times this demand has plunged nations into war.

In view of the foregoing, I have a definite plan to suggest—a plan for permanent peace through international co-operation in the conservation and distribution of natural resources.

National life everywhere is built on the foundation of natural resources. Throughout human history the exhaustion of these resources and the need for new supplies have been among the greatest causes of war.

A just and permanent world peace is vital to the best interests of all nations. When the terms which will end the present War are considered, the neutral nations should be in position to assist in finding the way to such a peace. That being so, it would be wise to prepare in time.

The proposal is that the nations of the Americas prepare now for an endeavour to bring all nations together, at the right moment, in a common effort for conserving the natural resources of the earth, and for assuring to each nation access to the raw materials it needs, without recourse to war.

In all countries some natural resources are being depleted or destroyed. Needless waste or destruction of necessary resources anywhere threatens, or will threaten, sooner or later, the welfare and security of peoples everywhere. Conservation is clearly a world necessity, not only for enduring prosperity but also for permanent peace.

No nation is self-sufficient in essential raw materials. The welfare of every nation depends on access to natural resources which it lacks. Fair access to natural resources from other nations is therefore an indispensable condition of permanent peace.

War is still an instrument of national policy for the safeguarding of natural resources or for securing them from other nations. Hence international co-operation in conserving, utilizing, and distributing natural resources to the mutual advantage of all nations might well remove one of the most dangerous of all obstacles to a just and permanent world peace.

The conservation of natural resources and fair access to needed raw materials are steps toward the common good to which all nations must in principle agree. Since the American nations are less dependent on imported natural resources than European nations, and since they are already engaged in broadening international trade through negotiated agreements, their initiative to such ends would be natural and appropriate.

The problem of permanent peace includes, of course, great factors which the foregoing proposal does not cover. But it does cover that factor which is certainly, in the long run, the most potent of them all.

If the foregoing proposal is adopted, facts in support of it will be needed, and a plan for assembling them. The formulation of a general policy and a specific programme of action would follow.

Facts for each nation separately, for groups of nations, and for the whole world might well be assembled under the general classes of forests, waters, lands, minerals, and wild-life. In very brief outline they should include: resources in existence; consumption; probable duration; waste; conservation, if any; necessary reserves; available surplus; present interdependence of nations in natural resources (raw materials), with the origin, destination, and quantities of imports and exports; present barriers to 'fair access'; and sources of pressure upon nations to acquire natural resources.

The information just outlined undoubtedly exists in sufficient detail for the present purpose, and can be put together without original investigation. It could well be done through a Commission appointed for that purpose representing all the American nations.

The gathering of information through the creation of such a Commission might, I believe, properly be recommended by the Eighth American Scientific Congress to the Governments of the American nations.

Formulation by the Commission of a plan and of recommendations to the American Governments for a general policy and a specific programme of action, including the presentation of the plan when prepared to neutral and belligerent nations, would follow.

Such a Commission would be of immense and lasting value to the American nations. It could not but advance their interests, both individual and mutual, in addition to opening a road toward a workable basis for permanent peace.

Finally, the situation in Europe and in Asia suggests that action for the purpose outlined above was never more necessary than at present.

THE UTILIZATION OF PETROLEUM GASES*

By Dr. A. E. Dunstan,

ANGLO-IRANIAN OIL COMPANY, LTD.

IT is interesting at the outset to realize the quantities involved in the problem of the utilization of natural gas. In 1938 there was a production of about 270 million tons of crude oil. Superimposed on the oil and in solution there is natural gas, and that gas production is estimated at an almost astronomical figure which may be compared with the ordinary coal gas production in the United Kingdom.

World production of petroleum 1937	276,000,000 tons
„ „ „ „ 1938	268,000,000 „
Annual world production of natural gas (approx.)	3,000,000,000,000 cu. ft
Annual world production of gas from cracking process	300,000,000,000 „
Coal gas produced in the United Kingdom in 1937	550,000,000,000 „

An oilfield has the following geological structure: an anticline, an impervious cap rock, gas dome and below that an oil-bearing structure, and farther down a water horizon the pressure of which forces the oil up into the drilled well. It is clear that a well drilled, for example, into the uppermost gas horizon will miss the oil and will lead to the diminution of gas pressure. It is, therefore, the business of the geologist and the geophysicist to indicate to the production engineers where to locate their wells.

The oil and gas coming up from the well pass into a separator, which may be upwards of 150 ft. in length; this takes off the high-pressure gas, up to two to three thousand lb. pressure, from the crude oil. Hence there remains a solution of gas in oil, together with free gas, mainly methane, coming off from it. The methane is thus separated, but obviously the oil itself must contain dissolved gas. There follows, therefore, a series of multi-stage

* Based on a Friday evening discourse at the Royal Institution.

separators in which the ethane, propane and butane can be removed from their solution in the oil. The various dissolved gases are thus released stage by stage. This low-pressure gas, which inevitably carries with it a certain quantity of low-boiling liquid hydrocarbon material, has now to be handled. The gas is passed up lofty towers counter-current to a stream of solvent oil passing downward. This dissolves all the volatile liquid matter that can ultimately be put into motor spirit; in effect, it is the removal of the last traces of liquefiable hydrocarbons from what might be called the true gases. There is a further stage; the volatile material thus recovered by distillation from the solvent contains material of low boiling point, and it is necessary in order to make the recovered volatile spirit into motor fuel, to remove from it material of specially low boiling point which seriously affects volatility of the finished petrol and would cause vapour lock in a motor-car engine.

The gases thus obtained from the crude oil are methane, ethane, propane and the butanes. They belong to the class of saturated hydrocarbons called paraffins. Etymologically the word 'paraffin' is, of course, entirely wrong. The word 'paraffin' implies something without any reactivity, with 'no affinity', whereas these gases have a great deal of reactivity. A special application of the dry gas, mainly methane, lies in its partial combustion to carbon black. The gas is burned against a revolving cooled surface and deposits what is in effect a very fine soot. This is scraped off, and finds a considerable outlet as a component with rubber of motor tyres. Further, when incorporated with oil, it yields printer's ink. There is also a rapidly expanding market for liquefied propane and butane —'bottled gas'—as a convenient domestic and industrial fuel. In point of fact, 150,000,000 gallons were sold in the United States in 1938. Notwithstanding that the dry gas is essentially paraffinic, in certain crudes—very limited in number—occurs the rare element helium, isolated by intense cooling and used as a lifting medium in airships by virtue of its low density. Finally, mention should be made of the occurrence of carbon dioxide and hydrogen sulphide in certain cases.

By the impact of high temperature the paraffin gases can be decomposed, in the first place to olefines by simple dehydrogenation and then to a complex mixture containing, in the main, aromatic hydrocarbons. For example, when methane is treated at a temperature of about 1050° C., benzene, toluene, xylene and styrene are obtained, together with naphthalene and anthracene. In effect, a sort of coal tar is produced in so far as the high-boiling components are concerned.

But it must be realized that methane is the most recalcitrant of the paraffins, and to-day pyrolysis is practised on material which is more reactant, for example, butane and propane, not only for the production of aromatic hydrocarbons but also for the preparation of olefines. Further, there are vast amounts of gases produced by what is called the 'cracking' process, that is, the production of light hydrocarbons from heavier oil. This gas is made up of olefines (ethylene, propylene, and the butenes, associated with the corresponding paraffins), and these are much more important starting materials for synthesis than straight natural gas.

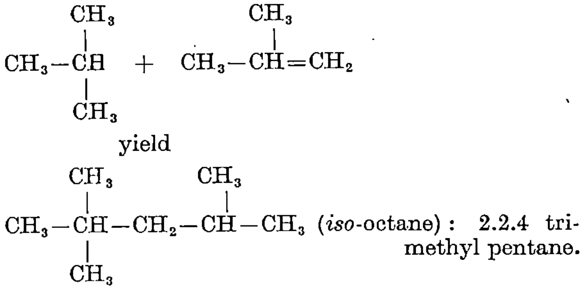
Cracking is a thermal decomposition; oil is converted by heat into material lighter, and into material heavier—into gas, motor-spirit and into heavy residue. The impetus to cracking actually began with the necessity of making more motor-spirit per gallon of crude oil. It was a quantity production.

Cracking was first carried out to get more motor fuel. Times have changed, and to-day the concern of the industry is to get material of higher octane value, which gives better performance in the engine. In other words, quantity is sacrificed to quality. The tendency to-day is to get higher and higher thermal efficiency, and higher and higher octane values. Most straight motor fuels are heavily cracked to get this higher performance. By such intensive cracking—known as the 'reforming' operation, about 30 per cent of the spirit comes away in the form of gas. When that gas is submitted to fractionation to separate heavier material from lighter, a cut of the C_3 and C_4 fractions is obtained; this is a potential source of high octane motor fuel and other synthetic derivatives. Hence the problem of making full use of the olefines, either straight olefines from the cracking operation, or olefines produced by the dehydrogenation of the paraffins present in the gases from the well must be considered; and so a series of operations arises concerned with the utilization of these derived unsaturated hydrocarbons.

This production of gaseous and liquid material by thermal decomposition or cracking is an example of Faraday's pioneering spirit. Faraday took the product of the cracking of fatty oils and obtained a series of fractions from the product, among which is one that boils at 180° F. Faraday put the samples thus obtained into a mixture of ice and salt, and obtained from one a crystalline material which he purified by squeezing away the accompanying oily matter, and this was benzene.

It has already been stated that the term 'paraffins' is a misnomer. For example, when *iso*-butane is brought into contact with *iso*-butene or its dimer in the presence of sulphuric acid as a catalyst, a remarkable combination takes place, for the tertiary atom of the *iso*-butane comes into reaction, and the result is a saturated hydrocarbon of a very high value in the internal combustion engine.

CATALYTIC ADDITION OF ISOBUTANE TO ISOBUTENE



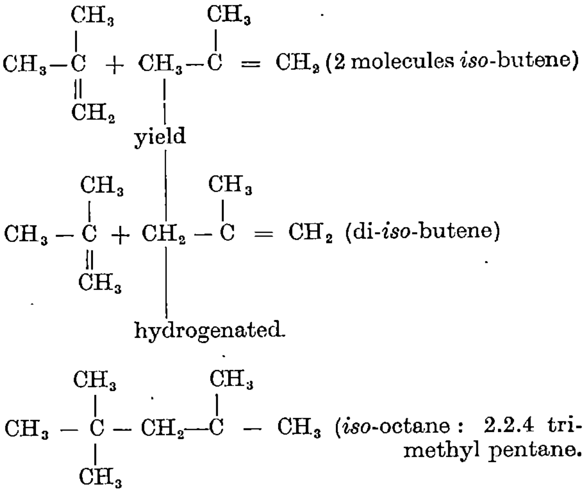
$$\begin{array}{l} \quad CH_3 \qquad\qquad\quad CH_3 \\ \quad | \qquad\qquad\qquad\quad | \\ CH_3-CH \quad + \quad CH_3-CH=CH_2 \\ \quad | \\ \quad CH_3 \\ \qquad\quad \text{yield} \\ \quad CH_3 \qquad\quad CH_3 \\ \quad | \qquad\qquad\quad | \\ CH_3-CH-CH_2-CH-CH_3 \ (\textit{iso}\text{-octane}):\ 2.2.4\ \text{trimethyl pentane.} \\ \quad | \\ \quad CH_3 \end{array}$$

It has long been known that the addition of an olefine to the aromatic hydrocarbon benzene can be achieved by the use of such a catalyst as aluminium chloride, but the simple addition of an olefine to a paraffin containing a tertiary carbon atom, using ordinary strong sulphuric acid as a contact medium, is new, and will have the most far-reaching effects on the petroleum industry.

Consider the potentialities. In the cracking process vast amounts are made of unsaturated hydrocarbons containing C_3 and C_4 derivatives. The natural gas of petroleum contains also great volumes of *iso*-butane. Also, it is quite certain that the even greater amounts of *n*-butane can be isomerized to *iso*-butane. The product of this addition reaction is in the main a C_8 paraffin of specially high 'octane value', that is, it has the capacity of notably withstanding detonation in the internal combustion engine. Of course there are also supplementary reactions, but careful distillation analysis indicates clearly various sharp fractions, mainly, in point of fact, isomeric octanes.

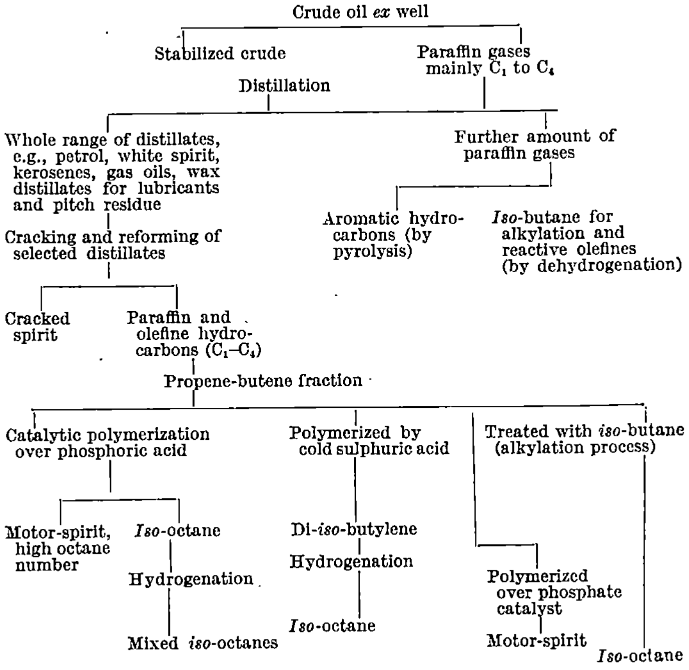
Furthermore, the polymerization of cracked gases is readily effected ; for example, ethylene (C_2H_4) can by the simple impact of pressure, temperature and time be converted into liquid fuel of the motor-spirit type. But a more effective way of converting C_3 and C_4 olefines into motor-spirit is by polymerization in the presence of a catalyst, and in particular one based on phosphoric acid. As a case in point, there has been used, with considerable success, copper cadmium phosphate. Such polymerization yields a motor-spirit of good quality, but if a selected cut or fraction of the total product is separated and submitted to hydrogenation, then again a C_8 mixed *iso*-octane is produced, just as it was in the case of the addition of butene to *iso*-butane. Further, if *iso*-butene also present in the C_4 cut from cracked gas is treated with cold sulphuric acid, it passes via tertiary butyl alcohol on warming to di-*iso*-butene (C_8H_{16}). This again, on being hydrogenated, yields *iso*-octane. So polymerization helps materially to increase the volume of high-octane gasoline.

DIMERIZATION OF ISO-BUTENE



$$\begin{array}{l} \quad CH_3 \qquad\qquad\quad CH_3 \\ \quad | \qquad\qquad\qquad\quad | \\ CH_3-C \quad + \quad CH_3-C \ = \ CH_2\ (2\ \text{molecules}\ \textit{iso}\text{-butene}) \\ \quad \| \qquad\qquad | \\ \quad CH_2 \qquad\quad | \\ \qquad\qquad\quad \text{yield} \\ \quad CH_3 \qquad\qquad\quad CH_3 \\ \quad | \qquad\qquad\qquad\quad | \\ CH_3-C \quad + \quad CH_2-C \ = \ CH_2\ (\text{di-}\textit{iso}\text{-butene}) \\ \quad \| \\ \quad CH_3 \\ \qquad\qquad\quad \text{hydrogenated.} \\ \quad CH_3 \qquad\qquad\quad CH_3 \\ \quad | \qquad\qquad\qquad\quad | \\ CH_3-C-CH_2-C-CH_3\ (\textit{iso}\text{-octane}:\ 2.2.4\ \text{trimethyl pentane.} \\ \quad | \\ \quad CH_3 \end{array}$$

Summing up then, a simple chart will illustrate how these various processes are effective in utilizing hitherto waste gases.



Crude oil *ex* well
Stabilized crude
Paraffin gases mainly C_1 to C_4
Distillation
Whole range of distillates, e.g., petrol, white spirit, kerosenes, gas oils, wax distillates for lubricants and pitch residue
Further amount of paraffin gases
Aromatic hydrocarbons (by pyrolysis)
Iso-butane for alkylation and reactive olefines (by dehydrogenation)
Cracking and reforming of selected distillates
Cracked spirit
Paraffin and olefine hydrocarbons (C_1–C_4)
Propene-butene fraction
Catalytic polymerization over phosphoric acid
Polymerized by cold sulphuric acid
Treated with *iso*-butane (alkylation process)
Motor-spirit, high octane number
Iso-octane
Hydrogenation
Mixed *iso*-octanes
Di-*iso*-butylene
Hydrogenation
Iso-octane
Polymerized over phosphate catalyst
Motor-spirit
Iso-octane

In so brief a résumé of the chemistry of these gases it is impossible to do justice to the development of a new synthetic chemistry based on the lower hydrocarbons. It is clear that it is possible to look forward to the time when the petroleum industry will furnish the starting-out materials for a whole range of products so diverse as ethylene glycol—the familiar anti-freeze in the motor-car; sulphur from the crude gases at the oilfields; synthetic motor fuel prepared from methane oxidized into a liquid fuel; the isomerization of normal paraffins; explosives such as T.N.T. (actually in fact produced in 1916); synthetic rubber, which is got by intensive polymerization of ethylene; high polymers of value in increasing the viscosity of lubricants; a whole range of derivatives of the aromatic hydrocarbons obtained by pyrolysis or by the cyclization and aromatization of straight chain paraffins—resins and plastics from the polymerization products of olefines such as *iso*-butene; acetylene by the dehydrogenation of methane; ether and ketones as solvents and high anti-knock fuel; alcohols, esters and a whole range of solvents through the halogen derivatives of paraffins; and the very striking synthesis of glycerol from propylene. The vast synthetic chemical industry based on coal tar is familiar to all. The new industry, based on petroleum, is certain to outstrip it in the magnitude of its operation and the variety of its products.

FORMS OF SOCIETY AND EUROPEAN RULE IN AFRICA

FOR some time now it has been evident that a more intensive study of the political institutions and systems of native Africa was an increasingly urgent necessity. New and more searching methods of investigation have brought out the weaknesses and misconceptions of the older material, while of the more recent accounts of African economy complying with the standards of modern research, the extent is inadequate for the requirements of comparative study on the lines laid down in the development of sociological theory as applied in the study of the simpler societies. In such studies African political institutions will ultimately assume a place of importance, for they range from forms which ally themselves to those regarded as among the more primitive in the constitution of human societies, to those which in their extent and organization have been pronounced worthy to rank as great kingdoms and even empires, though of barbaric type, such as the West African emirates. In these, as well as in the details of the adjustment of social forces in the less advanced societies, there is abundant evidence of the political genius of Africa, which is not without its lessons for the study of more advanced communities.

Apart from the requirements of scientific and comparative study, there is a practical reason why more detailed and intensive investigation should be undertaken. The adoption of Indirect Rule throughout the greater part of British Africa, and the possibility that other Colonial powers, in that co-operation in native administration to which we are pledged, may wish to assimilate their methods in some degree to those of British administration, render it imperative that the application of the principle of utilizing and adapting native institutions to the requirements of European control should be based upon precise knowledge of the nature of those institutions, and even more important, of the consequences and implications of any changes or adaptations in the native social and political relations inevitable under the impact of European control. This is all the more important as the effects of social disharmony extend their ramifications beyond the machinery for the preservation of law and order to provinces of amelioration and reform affecting the land, its utilization and preservation in good heart, hygiene, the well-being and education of the individual, his employment, the health of his stock and the like.

While the anthropologist in dealing with political and social institutions is concerned solely with scientific and objective study of the facts, it is inevitable that maladjustments and misunderstandings which arise out of European contacts and control should come under his notice. From these maladjustments even Indirect Rule is not exempt. It is, in fact, well known that both misunderstanding and friction have arisen from insufficient grounding in knowledge of the facts in certain situations, no preliminary or an insufficiently intensive survey having preceded introduction of this system of rule, or administrative co-operation. Too great reliance has been placed upon an assumed universality of the authority of the chief in African society; and this has been allowed to warp judgment in assessing the bearing of facts not always perfectly understood. Comparatively unimportant individuals have been given official status, while the real seat of tribal authority, sometimes with native connivance, functions undiscerned behind a veil. In the result, what emerges is not Indirect Rule but a purely British bureaucratic system.

This applies also under the French administrative system, for which its admirers have sometimes claimed that it approaches Indirect Rule without some of its more obvious disadvantages.

Something more than a beginning—indeed a substantial contribution towards the detailed anthropological survey of African societies which should form the basis of future post-War administration in Africa—has been made in a volume issued by the International Institute of African Languages and Cultures under the joint editorship of Dr. E. E. Evans-Pritchard and Dr. M. Fortes*, with a foreword by Prof. A. R. Radcliffe-Brown on the general methods of sociological inquiry as applied to simple societies. Here are given in condensed form the results of field investigations by different observers into the political systems of eight widely distributed African peoples. These studies cover South Africa (Zulu, Ngwato of Bechuanaland, Bemba of North-Eastern Rhodesia), East Africa (Ankole of Uganda, and Bantu Kavirondo), West Africa (Kede, Tallensi), and Sudan (Nuer). Although not completely comprehensive as to type, as the editors point out, the eight societies afford a general picture of the main forms of African political systems.

The eight types of political systems here described fall into two groups. Of these, the first includes those in which the maintenance of law and order and the dispensation of justice are dependent upon a centralized organization culminating in a paramount chief who rules with the assistance of a council and through a number of regionally distributed subordinate chiefs. Such a system, obviously, lends itself to the requirements of European rule. In the second group there is no such centralized organization with a supreme head. The society is organized in accordance with lineage and is 'segmented', each group being autonomous and independent of the others. Law and order are maintained by a nice adjustment of interests at each and every point of contact between groups. In such a system, European control, either through lack of understanding or through administrative requirement—sometimes both—has constituted headmen functioning as do the chiefs of the first group in relations between administration and people.

In estimating the value and effect of Indirect Rule as a mode of administration which has as its object that of introducing the minimum of disturbance into the economy of tribal life through European control, there is a number of important considerations to be taken into account, of which the most important is the fact that the power of the paramount chief is by no means absolute. By an extensive system of check and countercheck—the council, queen's courts, the rights, duties and interests of officials and subordinate chiefs and the like—there is throughout the community a balance of power which not only limits the power of the chief, but also ensures the continuity and preservation of custom, secures the effective representation of every grade of society in the general direction of affairs, and in the ultimate analysis places what would correspond to 'sovereignty' in the hands of the people. It is inevitable that this delicate adjustment should suffer dislocation under European control. Even Indirect Rule cannot avert the disturbance involved in depriving the chief of the power of initiating legislation independently and of making war. In the result, in the societies of the first category mentioned above, the chief has become a buffer between administration and people, who on whichever side his sympathies lie—and usually and naturally they are with his own kin—is suspect to both, or at least his actions subjected to strict supervision on one side, carping criticism on the other, even or most often when officially dictated. No less important is the fact that the religious and symbolic bond centring in the chiefly office, which so often binds together African societies of the centralized type, is weakened beyond repair.

It is inevitable that some measure of friction and disturbance must arise in African societies when under European control; and Indirect Rule, which aims at respecting African institutions, so far would seem to have been the most successful in minimizing its effects. Where we now stand, however, in our relations with other powers ruling in the greater part of Africa, opportunity will be afforded, when other preoccupations are less insistent, to consider what forms of control will best promote the future prosperity of the African. To attain this end there are certain essentials. First, full and free co-operation between all European powers administering African territory, not necessarily to secure uniformity in administrative method, but rather to ensure that such forms of rule as are applied should be most suitable to the character and circumstances of the governed in each instance. Secondly, and following from this, that decision should be made only after close intensive study of the respective native institutions, cultures and modes of thought; and thirdly, since through European contact and control change must come, that that change should be canalized in such direction as sociological and economic research may indicate as likely to enable the African best to bear his part in world economy. The severest stricture on Indirect Rule which its critics are in a position to make is that it lacks direction.

* African Political Systems. Edited by Dr. M. Fortes and Dr. E. E. Evans-Pritchard. (Published for the International Institute of African Languages and Cultures.) Pp. xxiii+301. (London: Oxford University Press, 1940.) 15s. net.

OBITUARIES

Dr. R. J. Lythgoe

By the death of Richard James Lythgoe, the subject of special sense physiology has suffered a most severe loss. Dr. Lythgoe was forty-four years of age, and received his education at Mercers' School and Trinity College, Cambridge, the latter phase being interrupted when, at the age of nineteen, he joined the R.G.A., in which he served throughout the War of 1914-18, experiencing heavy and nerve-shaking fighting.

Returning to Great Britain, Lythgoe studied medicine at University College Hospital, and took the Cambridge M.B., Ch.B. in 1924. Almost immediately afterwards he joined the staff of the Department of Physiology at University College, as Sharpey scholar, and held that post for a year. His first paper, published then, in collaboration with another, dealt with the pulse-rate and oxygen-intake during recovery from severe exercise. It was evident, however, that his interests lay in another direction, for in 1926 he was awarded a Beit Memorial research fellowship, and commenced the study of the physiology of the special senses, in which branch he worked for the remainder of his life, and gained international distinction. All his work was carried out at University College, London, and he was a part-time teacher, and later University reader in the physiology of the special senses, in the Department of Physiology, Pharmacology and Biochemistry of the College. He held Beit fellowships and senior Beit fellowships from 1926 until 1933, after which time his researches were in part financed by the Medical Research Council and by the Rockefeller Foundation.

It is no exaggeration to say that Lythgoe was one of a few physiologists in Great Britain who have done signal work for their subject by resuscitating an important branch of it from a state of neglect into which it had fallen during the preceding decades. In some two dozen papers he, with collaborators, covered many important aspects of special sense physiology, many of them of clear practical importance. For example, the work on the measurement of visual acuity, or that on the adaptation of the eye in relation to the critical frequency of flicker, had valuable practical bearings. Other work, particularly that on which he had been engaged just prior to the present War, and which was undertaken jointly with Dr. C. F. Goodeve, dealt with the photochemistry of visual purple, and was of outstanding theoretical importance.

Many advanced students during the past twelve years will remember Dr. Lythgoe's annual public lectures on the physiology of vision, and the practical instructions and demonstrations with which these were supplemented, and in which his flexible versatility in laboratory work was so strikingly illustrated. His wife, Dr. Katharine Tansley, whom he married in 1931, was one of his early pupils at these classes, and a constant collaborator with him in furthering the study of the branch of work in which he had engaged.

Lythgoe was an unexceptionable colleague, loyal, modest and always helpful and dependable; capable of fine and artistic appreciation and a consummate investigator. He could on many occasions have occupied a chair of physiology, but preferred the path of pure research unhampered by administrative duties or by the labour of teaching outside his real interests. When he was persuaded to undertake administrative work, however, he did it with the zeal and thoroughness which characterized all his doings. His work as a joint secretary of the Physiological Society, and as a member of the editorial board of the *Journal of Physiology* are instances of his faithful work. At the time of his death he was engaged on work of national importance.

Dr. Lythgoe died on February 28, and leaves a widow, a son and two daughters, the younger born in January last. To them we extend our very sincere sympathy in their bereavement.

Prof. Felix Plaut (1877-1940)

Prof. Felix Plaut, whose death occurred on June 27 at Epsom, where he had been engaged in research work on the reaction of vitamin C to neurological and psychiatric conditions, was born at Cassel on July 7, 1877. He studied medicine at Geneva and Berlin, and qualified at Munich in 1902. His principal work, which was carried out at the Robert Koch Institute for Infectious Diseases in Berlin and at the Psychiatric Clinic at Munich, where he was appointed to an additional professorship in 1915, was concerned with the study of the nervous system, especially the cerebrospinal fluid, and the serological and psychiatric aspects of syphilis. His chief publications were on the Wassermann reaction in psychiatry (1909), examination of the cerebrospinal fluid (1913), hallucinations in syphilis (1913), general paralysis in negroes and Indians (1926), and the treatment of syphilitic mental disorders. For several years he was one of the editors of the *Zeitschrift für die gesamte Neurologie und Psychiatrie*.

We regret to announce the following deaths:

Mr. J. H. Fleming, formerly president of the American Ornithological Union, honorary curator of the Royal Ontario Museum of Zoology, on June 27, aged sixty-seven.

Prof. W. Frecheville, emeritus professor of mining in the Royal School of Mines, on July 30, aged eighty-six.

Surgeon Rear-Admiral E. L. Pearce Gould, formerly dean of the Middlesex Hospital Medical School, on August 1, aged fifty-four.

Prof. Hans Virchow, professor of anatomy in the University of Berlin.

NEWS AND VIEWS

The Hon. Gifford Pinchot

THE idea of conservation of natural resources is of American origin, having been formulated by the United States Forest Service so recently as 1907. The history of the development of this idea since that date, and attempts to use it as a basis for international unity and amity, is described by the Hon. Gifford Pinchot on p. 183 of this issue. Dr. Pinchot continues with a valuable proposal to utilize and develop even further this idea at the peace which will follow the present conflict. No one is better qualified than Dr. Pinchot to press these proposals, which are very worthy of consideration not only by men of science but also by all who can justifiably claim a hearing when terms of peace are up for consideration. Dr. Pinchot was a forester in the U.S. Department of Agriculture during 1898–1910. He was commissioner of forestry, Pennsylvania, during 1920–22 and governor of that State during 1923–27 and 1931–35. For a long period he held the chair of forestry in Yale University and has served on several National Commissions of Conservation. Among his publications are books on forestry and one entitled "The Fight for Conservation" (1909).

U.S. National Defence Research Committee

IT is announced by Science Service that the following committee has been appointed in the United States to correlate "scientific research on the mechanisms and devices of warfare":

Dr. Vannevar Bush (chairman), president of the Carnegie Institution of Washington, formerly dean of the faculty of engineering at the Massachusetts Institute of Technology;

Prof. Richard C. Tolman (vice-chairman), dean of the graduate school and professor of physical chemistry and mathematical physics at the California Institute of Technology;

Dr. Irvin Stewart (secretary), formerly Federal Commissioner for Communications and chairman of the Committee on Scientific Aids to Learning;

Rear Admiral Harold G. Bowen, director of the Naval Research Laboratory, Anacostia, D.C.;

Conway P. Coe, U.S. Commissioner of Patents;

Dr. Karl T. Compton, president of the Massachusetts Institute of Technology, formerly professor of physics at Princeton University;

Dr. James B. Conant, president, formerly professor of organic chemistry, Harvard University;

Dr. Frank B. Jewett, president of the Bell Telephone Laboratories;

Brigadier General G. V. Strong, assistant chief of staff, U.S. Army.

Assessment of Public Opinion

RECENT discussions in Parliament have directed critical attention to the use of 'market research' methods by the Ministry of Information for the purpose of assessing public opinion. The political aspects of the inquiries naturally loomed largest in the debate. It is well to remember, however, that the question is not one solely of the political repercussions of applying a mature scientific procedure. The scientific basis of such work also deserves scrutiny. In at least two important respects the method is scientifically still in its early stages. First, it has not fully explored the possibilities of error which lurk in its basic tool, namely, the question. Secondly, it seldom has any reliable criterion for testing the validity of its results. The work of Muscio (following Stern and Lipmann) demonstrated so long ago as 1916 that the form in which a question is worded has an important effect on the information which it elicits. Muscio showed the importance of points which go far beyond the avoidance of what common sense and legal rulings recognize to be suggestive questions. Unaccountably, Muscio's work has not been carried further by later psychology. Still more unaccountably, no means have been devised of putting his findings to practical account in social inquiries.

Measures of public opinion could be shown to be valid if they made possible the accurate prediction of public action. But this test can seldom be applied. Occasionally the results of elections have been predicted, sometimes with striking success, sometimes with inaccuracies which are traced to the underestimation of an apparently minor factor in the situation. Moreover, public opinion is fluid, a continuous activity rather than a state; and therefore a snapshot which is accurate at a given moment may not have predictive value for public action even a short time later. The importance of this factor will depend partly upon the extent to which the topic investigated has already been canvassed by the public. To take an example from the discussion in Parliament, public opinion on B.B.C. variety programmes is relatively mature; but on the question of whether it is better to fetch our own milk cheaply or to pay a little for delivery, opinions must have been collected from people to whom the question had never before occurred and who had never discussed it among themselves. (Further, the question seems to have been asked at a time of year when the mornings are light and the weather is fine.)

In the main, this method of inquiry has established itself through the belief of business men that market surveys do give them the information that they need for their sales policies. But it has to be remembered that in market research pure inquiry is never for long dissociated from efforts at moulding opinion. It is immediately followed by extensive advertising and propaganda which, in presupposing the truth of the survey findings, may in fact make them true. In the political field the same necessity to follow inquiry by persuasion will always make it difficult to test the findings of the inquiry. The uncertainty of these methods must not be exaggerated. But it should be realized that there is scope for much improvement before they can be regarded as scientifically mature.

Welfare of Aliens

An Advisory Council of Aliens has been appointed by the Secretary of State for Foreign Affairs. This Council, which is under the chairmanship of Lord Lytton, and will work in close association with the Foreign Office and other departments concerned, will advise the Home Office on the general welfare of interned aliens, make recommendations on finding employment for internees, and suggest measures for maintaining their morale and binding them more closely to the cause for which Great Britain is fighting.

A Home Office White Paper (Cmd. 6217. London: H.M. Stationery Office. 1*d.*) has been issued showing the conditions under which German and Austrian refugees at present interned may be released. The regulations now issued apply only to "C Class" internees, but it is stated that they are not to be regarded as final. Among those who may now apply for release are those who occupied key positions in industries engaged in work of national importance, skilled workers in agriculture, commercial food-growing and forestry, and scientific and other research workers and persons generally with academic qualifications for whom national work in their own fields is available. With regard to the latter groups, special committees are being set up by the vice-chancellors of the universities, the Royal Society and the British Academy to consider applications and to submit recommendations to the Home Secretary. These new regulations seem to provide the necessary safeguards of national security required in any relaxation of the order for general internment of aliens, and should meet with general approval.

An International Labour Force

Speaking in the House of Commons on August 1, Mr. Bevin, Minister of Labour, announced that he has set up an International Labour Branch as part of the employment department of his Ministry. The purpose of this branch is to organize the man-power of allied nations and of other well-disposed persons of foreign nationality in Great Britain. It is hoped to obtain full knowledge of those available for employment and to seek suitable openings for them in industrial and other work. Co-operation is to be maintained with the Allied Governments and other national authorities in Great Britain, and Mr. Bevin also hopes to have the advice of representatives of trade unions of foreign countries. He was very emphatic that the new branch would have nothing to do with internees; release of aliens and their supervision generally is a matter for the Home Office. Once an individual has been passed by the Security Department, then he becomes available for consideration by the Ministry of Labour. At this stage, Mr. Bevin said he proposed to dispense with the terms 'aliens' and 'refugee', and to refer to such individuals as an 'International Labour Force'. This development, coming at the same time as the announcement of limited release of German and Austrian refugees, shows that the problem of dealing with the unfortunate people who have been driven from their homes by Nazi and Fascist persecution is being given careful consideration. They have come to Great Britain for freedom, and while they will recognize that the special needs of the times make restrictions of various kinds necessary, they will appreciate the opportunity which is now to be given them of taking an active part in the struggle against totalitarian domination.

Sales Tax on Books and Periodicals

The case for withholding the imposition of the proposed purchase tax from printed books and periodicals was put before a private meeting of Members of Parliament held on August 6. As a result of the meeting, Mr. Kenneth Lindsay obtained support for an amendment which he is to submit proposing to omit printed books, music, pamphlets and leaflets from the schedule of taxable articles, and P. J. Loftus put forward another amendment which would exempt weekly, monthly and quarterly technical, scientific and trade journals retailed at not less than 6d. An amendment to exempt newspapers and periodicals is to be moved by Mr. Mander. Nature has already discussed the probable effects of the imposition of a sales tax on books and other publications (May 11, p. 719, and August 3, p. 160). On general as well as scientific grounds, the imposition of a tax on books is a bad thing, which even at the present time cannot be justified on grounds of financial expediency.

African Studies and the War

Lord Lugard, as chairman of the Executive Council of the International Institute of African Languages and Cultures, announces in the current issue of *Africa* (13, 3; July 1940) that the work of the Bureau and the publication of its periodical *Africa* must now cease for the duration of the War. In October last it was stated that it was hoped to carry on the Institute's work without serious interruption. Recent developments, however, have made international co-operation impossible, and it has been deemed advisable in the circumstances to cease work until after the War. Certain of the special publications of the Institute, which have proved so valuable to students of African peoples, are in an advanced stage of preparation and will be published as soon as possible—a book on African political systems, recently published by the Institute, is discussed on p. 188 of this issue of Nature. Further, several research fellows are engaged in writing up their field-notes. Dr. Nadel's notes on the Nupe of Northern Nigeria, and those of Mr. and Mrs. Krige on the Lovedu of the Northern Transvaal have been completed; but Dr. Margaret Read is still engaged on the results of her research in Nyasaland, and more especially on the part she took in the recent nutrition survey of that territory.

While those who have followed the work of the Institute, more especially since the receipt of the generous grant for field-work from the Rockefeller Trustees, will deeply regret this interruption, temporary though it may be, in its activities, they must, of course, accept the facts of the situation and realize that the international co-operation which has given its deliberations breadth and understanding is now an impossibility. At the same time, it would seem desirable that the intermission of activity should not be complete. It is generally conceded that the time for planning for peace is now, and not at the close of hostilities. This applies no less to Africa than to Europe. A planning that begins with the peace will be too late to cope with the changes in African societies, which if the aftermath of the War of 1914–18 is a criterion, will ensue all too rapidly.

Storage of Electric Power in the Ruhr

THERE has been a rapid increase in recent years in the use of electricity in steel manufacture in Germany. This 'electric steel' has a very uniform structure, but, if the cost is to be comparable with that produced by other means, the factor of safety has to be reduced. With so many high-frequency furnaces going intermittently, the power supply systems must be subjected to considerable peak demands. This is especially the case in the Ruhr, where, although there is a plentiful supply of coal, considerable reliance is placed upon the water-generated supplies from Austria to meet the heavy peak demands. The largest and one of the most interesting of the storage stations is situated at Herdecke on the banks of the Rhine about six miles south of Dortmund and nearly twenty miles east of Essen. It is connected with the control point at Brauweiler, which is on the Rhine between Cologne and Dusseldorf. By accumulating water in an elevated reservoir by means of pumps and the erection of the Herdecke power storage station and others in the district, the peak-load problem has been solved satisfactorily. Interesting details of this station are given in the *Electrician* of July 26.

The upper reservoir of the Herdecke plant, covering an area of 18 acres, is designed to permit the full development of the available power. The maximum variation in water-level from empty to full is 65 ft. The maximum pressure head between the lower reservoir, Lake Hengsty, and a full upper reservoir is 540 ft., and the minimum head available is thus 475 ft. The power house is 500 ft. in length and each machine has an axial length of 85 ft. The station can be automatically switched from pumping to turbine operation in two minutes, and during pumping the turbine discharges are closed by means of flaps. The upper reservoir is oval in shape and is about 800 ft. above sea-level; this necessitated the excavation of 1,300,000 cubic yards of rock. The entire concrete surfaces coming into contact with water have been rendered impervious by means of a bitumen spray treatment. The work was commenced at the beginning of September 1927, and the station was brought into partial operation in December 1929, full operation following about a year later. The characteristic feature of this type of station is that at times of low power consumption the waste current of the water stations, or the increased night output of the steam stations, is employed to pump water back into the storage reservoir.

This Season's English Herbs

MORE than usual interest will be shown this season in the English harvests of vegetable drugs, and it is now possible to judge from reports by herb farmers on the prospects of their crops what the harvests are likely to be, provided weather conditions for collection are favourable. Fair supplies are promised of those old-fashioned medicines such as hyssop, rue, wormwood, comfrey, balm and dill, but the same cannot be said of chamomile, the prospects of which are disappointing, an outlook that is all the more unfortunate since it is impossible to obtain supplies from Belgium. Indeed, it would seem that those who have pinned their faith, in the past, to chamomile tea will have to try one of the more modern remedies which are not so scarce. What is still more unfortunate is that on some herb farms the severe frost last winter destroyed the main belladonna plantations so that very little leaf—which is so badly wanted because of the absence of imports of the Continental plant—could be collected this season. It is satisfactory to know that the young belladonna plants of this year's sowing are looking well.

Growers of henbane report that there was a good crop of second-year biennial plants, and leaf and flower of good alkaloidal content have been harvested; after a time of drought, rain came to save the first-year seedlings, which will provide leaves for autumn drying. Prospects of a crop of high-testing digitalis leaf are favourable. Aconite is said to be looking well and there is a full crop of valerian. Having regard to the stoppage of supplies of lavender oil distilled in the Grasse district of the Alpes Maritimes, it is well to learn that English lavender plants stood up well to the hard winter and the flowers have bloomed earlier and, in some cases, better than usual; a fair yield of English lavender oil may be expected for this season; more of the flowers will go to the still and less to Covent Garden in bunches for street vendors, and thus at least part of the shortage due to the lack of French oil will be made good.

Notation for Tapping Systems of the Rubber Tree

THE scientific groups dealing with rubber production in Ceylon, Malaya and Netherlands East Indies have recently adopted a common notation for expressing the varied tapping systems by which the crop from Hevea is obtained. Attention was directed by Evan Guest, of the Rubber Research Institute of Malaya, to the confusion and ambiguity which existed because different centres had developed their own nomenclature without plan, and his suggested scheme, modified by the co-operation of others, has now been accepted (*J. Rubber Research Inst. Malaya*, 9, 142–170; 1939: 10, 16–33; 1940). This will mark a great advance in co-ordination of scientific records of yields from Hevea, for the fundamental factor, namely, intensity of tapping, is simply and accurately brought into the required prominence.

First the type of cut is identified by an initial letter, followed by the figure expressing the fraction of the tree circumference which is covered. Then the periodicity of tapping and resting is expressed by further fractions showing the frequency of tapping and the relation of tapping to resting periods. Finally, simple conventions define the arrangement of the panels, a matter which assumes special importance for the multiple cuts of the so-called slaughter systems by which old trees are drained before re-planting. Standard intensity is defined as a half spiral tapped alternate days without rest (that is, equivalent to one quarter cut per day) and the relative intensity of the system is easily arrived at by scanning the formula. As examples: "$S/1$, $d/3$, $4m/6$, 89%" signifies a full-circumference spiral cut tapped every third day for a period of four months in a cycle of six (two months rest), giving 89 per cent of the standard intensity; or "$S/3$, $d.2$ ($3 \times 6m/18$) 67%" indicates three panels of one third spiral cut, each one being tapped every second day for six months taking them in rotation. The amount of tapping can be expressed in circumference units (fractional length of cut multiplied by number of tappings), using the actual instead of the ideal number of tappings.

Most rubber estates keep full records which should potentially be a voluminous source of information, but the variables are so many and have in the past been so hazily defined that the scientific value of such records has often proved disappointingly small. Guest's notation will mark a great step forward in the task of making records both intelligible and comparable.

Golf Green Research and the War

THE revised values which the war places upon various activities have caused the managers of the Board of Greenkeeping Research to review the position of the Research Station at St. Ives, Bingley, Yorks. The experimental plots at this centre have been built up over a period of eleven years, at a cost of more than £26,000, and have provided valuable new knowledge about the ecological interaction of plants grown in compact formation, and about the practical treatment of greens. Much of their scientific value lies in their long term of treatment, and it is gratifying to learn that they are to be carried on, even if the need for economies should curtail the Station's other activities. It is also useful to remember, in the present intensity of the war effort, that the Station has contributed to a fundamental understanding of grass ecology which could be applied to increase food production on some of the poorer grassland of British uplands. Its researches on pests and diseases of grassland could quickly be turned to the aid of agriculture, and the Station has further adapted itself to war conditions by working on the best methods of pasturing sheep on golf courses, and giving advice upon minimum upkeep during the present difficult times.

Practical Applications of Horticultural Research

IN time of war there is a special need for the dissemination of the findings of scientific research, and in no field is this more true than in agriculture and horticulture. The application of known facts is often more important than the making of new discoveries. Following this principle, the John Innes Horticultural Institution is preparing a series of leaflets embodying in condensed but adequate form the results of some of the most practically important lines of investigation which have been followed in recent years. The first three of these leaflets have already appeared and deal respectively with the John Innes composts, soil sterilization for pot plants and the John Innes soil sterilizer.

Every horticultural grower is aware of the valuable work done by the Institution in devising two standardized composts, one for seed sowing and one for potting. These composts replace the bewildering array of mixtures recommended in horticultural text-books and may be used with success for every class of plant. No less important is the work of the Institution on the sterilization of potting soils, which has amplified and extended that of the Cheshunt Experimental Station. The principles of sterilization as applied to the John Innes composts are outlined in Leaflet No. 2, while No. 3 gives details of the home construction and the use of the specially designed John Innes soil sterilizer.

Prof. Richard von Krafft-Ebing

PROF. RICHARD VON KRAFFT-EBING, an eminent German psychiatrist and a pioneer in the scientific study of sex, was born at Mannheim on August 14, 1840. He received his medical education at Heidelberg under Fredreich and at Zurich under Griesinger, and after qualifying at Heidelberg in 1863 spent five years as an assistant in the Illenau Asylum. In 1872 he was appointed professor of psychiatry at the recently founded University at Strasbourg, and in the following year he accepted an invitation to occupy the corresponding chair at Graz, where he remained until 1889, when he succeeded Leidesdorf at the First Psychiatric Clinic at Vienna. In 1892 he succeeded Meynert at the Second Psychiatric Clinic, which he directed until his retirement in 1902. He died on December 22, 1902.

Kraft-Ebing was equally eminent as a research worker and clinical teacher, and gained a well-merited reputation not only as a psychiatrist but also as a criminologist and neurologist. He is best known for the work entitled "Psychopathia Sexualis", of which the first edition appeared in 1886 and the seventeenth posthumously in 1924. It was translated into English, French and Italian. His other works were "Melancholie" (1874), "Lehrbuch der Psychiatrie" (1879) which was translated into English and French and went through seven editions, and "Eine experimentelle Studie auf dem Gebiete des Hypnotismus" (1888), which was also translated into English. At the International Medical Congress at Moscow in 1887 he read an important paper on the causation of general paralysis which, as the result of his own experience, he proved to be the joint product of "syphilization and civilization". He was an honorary member of the medico-psychological societies of London, Paris, Rome, Amsterdam, Moscow, New

York and Chicago. A monument was erected to him in Vienna in 1908, when an address was delivered by his successor, Prof. Wagner von Jauregg.

Palæozoic Coral Genera

A COMPLETE list of the Palæozoic coral genera has been carefully prepared, correctly named, and supplemented by references to authors, synonyms, localities and published works ("Index of Palæozoic Coral Genera." By William Dickson Lang, Stanley Smith and Henry Dighton Thomas. Pp. vii+231. London: British Museum (Natural History), 1940. 15*s*.). Genotypes are arranged in the alphabetical order of the trivial names, followed by the generic name and its author. In the list of literature it is useful to have a record of the genera described in each work. Dr. Lang presents the list as the foundation of future work on the phylogenetic classification of the corals. Although he examines critically the gradations and trends among Tabulate and Rugose corals, he and his collaborators leave the interpretation of the facts to others. The most laborious part of the task has, however, been performed for them. More than fifty generic names are pre-occupied by members of other phyla, and of the corals themselves, nearly twenty names are *nomina nuda*. This sifting and purifying should be of lasting benefit to workers on the group.

Intelligence among Australian Aborigines

THE difficulties of applying intelligence tests to primitive peoples with a view to comparative study are notorious, and much ingenuity has been employed in devising tests which are immune from the vitiating factor of differences in the cultural background of the individuals or groups which it is sought to compare. The pioneer work of Dr. S. D. Porteous among Australian aborigines may be recalled in this connexion. Even more remarkable results, however, have been obtained by a recent expedition to the north-western regions of the Continent, sent out by the University of Western Australia, and consisting of three members of the Psychology Department, Mr. N. G. Trayten, Dr. D. W. McElwain and Dr. H. L. Fowler. Under the advice and with the co-operation of Dr. D. S. Davidson, assistant professor of anthropology in the University of Chicago, experiments were made in the application of intelligence tests which had not previously been tried with the Australian aborigines.

Not only was it desired to determine whether these tests were likely to prove more suitable for work with primitive peoples than those generally in use, but also whether they appeared to confirm the low estimate of aboriginal intelligence afforded by previous investigations. In a preliminary report on the work of the expedition, Dr. Fowler (*Australian J. Ser.*, 2, 5; 1940) records that, of the various tests applied experimentally, the Alexander Passalong test, involving the arrangement of coloured blocks in boxes, the Ferguson form boards, in which insets have to be placed in proper position, and the cube construction test, proved the most suitable, the second being the most satisfactory. Eighteen males and thirteen females were tested. They were of different ages, all but four being adults. In the results the interesting point lies not so much in the average mental age attained as in the range over which the scores spread, while considerable variation was noted in the different tribes. Still more remarkable is the fact that eight of the subjects in one test and five in another scored a mental age of fourteen or over, which indicates that they are at least at or above the level of the average white adult. From these results, which are in agreement with opinions expressed by squatters as to aboriginal abilities, Dr. Fowler draws the conclusion that further investigations should be undertaken in order that, if these preliminary results are confirmed, steps may be taken to foster the development of such abilities.

Roadwork and Bridges in Hungary

FOLLOWING its established custom, the municipal administration of Budapest has again called for tenders for dust-proofing the macadamized roads in the city. According to *Roads and Road Construction* of July, the proposal was to treat 522,000 sq. kilometres of roads with oil while the remaining 320,000 sq. kilometres of road requiring dust-proofing treatment would have been treated with tar. The bids proved that the price of oiling would have been one third higher than last year, while contractors also insisted on various disadvantageous clauses and conditions. The municipality has therefore decided to apply dust-proofing treatment to a total of 550,000 sq. kilometres of road surface only, using tar throughout. The Ministry of Commerce has issued a series of important commissions for the construction or reconstruction of roads and for two new bridges spanning the Danube and the Tisza respectively. The total commissions amount to well over seven million pengoes.

The new bridge over the Danube at Medve will cost more than two million pengoes, while that over the Tisza, in the Hungarian lowlands, will cost nearly 860,000 pengoes. The Danube bridge will be erected by the Hungarian Waggon and Machine Factory, while that on the Tisza will be built by Ganz and Company, of Budapest. The number of road contracts so far allotted is fourteen, and they have been awarded to the same number of different firms, partly to joint stock companies and partly to individuals. The majority of the roads will have concrete surfaces, although a few will have stone surfaces. The total amount of the fourteen orders is about 500,000 pengoes.

Swiss Postal Railway

IT is stated in the *Bulletin* of the Oerlikon Co. that an underground railway has recently been built in Zurich for the conveyance of letters and express packets between the branch post office at the main railway station and the Sihl post office, which are about three quarters of a mile apart. The railway is practically automatic. A driverless electric track is set in motion by pressing a push button on the main control panel. At the railway station terminus the track runs on to a lift, which operates automatically, rising to the level of the post office above. The railway is operated by a three-phase 220-volt, 50-cycle supply. This obviates the need for converter sets or special gear on the motor track for reversing. To reverse, all that is necessary is to interchange the connexions of two phases of the supply.

The motor-truck has two axles, one of which is coupled through gears to a 3·5 h.p. three-phase induction motor, giving the truck a speed of 14·4 ft. per sec. The other axle is driven by a 1 h.p. motor for running at low speed (0·98 ft. per sec.). The latter motor is brought into operation at the stations by means of an electro-magnetic coupling controlled by a change-over switch, which is actuated by a roller contacting with a third rail in the station sections. The truck is fitted with a mechanical brake operated by spring force. The order for the whole installation was placed with the Oerlikon Co.

Catalogue of Meteorites

The British Museum (Natural History) Catalogue of Meteorites was issued in 1923 and a first appendix appeared in 1927. A second appendix, compiled by M. H. Hey, has now been published by the Trustees of the Museum (1940, pp. 136, price 5*s.* net). It includes particulars of all meteorites described since the appearance of the first appendix up to the end of September 1939. Additions and corrections to some of the earlier entries have been made and a separate list of meteorite craters has been included. It is interesting to note that the catalogue and its appendixes now contain entries for 1,251 reasonably well-authenticated falls, of which 758 are represented in the Museum collections, and for a further 98 'doubtful' and 'paired' falls, of which there are 24 in the collections. Of the 51 'doubtful' falls, a few may not be meteorites, others have never been adequately confirmed or described, and others may have names that may be synonymous with those of falls otherwise recorded. The 47 'paired' falls are pairs or groups of falls which are possibly or probably identical; these have been counted only once in the totals. Falls reported in ancient histories and objects of worship in ancient temples thought to have been meteorites have not been included, except in the case of *Jalandhar*, which fell in the Punjab in 1621 and was forged into sword blades; in other cases the data are too vague and uncertain.

Extra Fat Allowance for Diabetics

Mr. Boothby, Parliamentary Secretary to the Ministry of Food, has stated in the House of Commons that the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council has advised the Minister of Food that persons suffering from diabetes mellitus should be allowed two extra butter and margarine rations, totalling 12 oz., each week. The necessary arrangements for the issuing of the supplementary rations by food executive officers has been made.

Recent Earthquakes

On July 30, violent earthquakes occurred on the central plateau of Anatolia. Twelve villages including Peyk were destroyed near Yozgad, the shock also being felt at Ankara, Erzinjan, Tokat, Kayseri, Amasya, Sinop, Istanbul and intervening places. Three hundred people are reported to have been killed and several hundreds of others injured. The epicentre of the shocks appears to have been near Yozgad, which is not far from Erzinjan, the centre of the greatest of all Turkish earthquakes on December 27, 1939 (Nature, January 6, p. 13). The present shocks cannot be considered as aftershocks of the December 27 earthquake nor are they so intense, but they point to the same general instability of the whole region at the moment, of which all the shocks are the result. It must also be noticed that such a terrific earthquake as that of December 27 would itself give rise to instability which would persist for a considerable time and give rise to earthquake shocks in general not so intense as the original one. Aftershocks of the earthquakes of July 30 were continued on the next day.

An earthquake of considerable severity was experienced in western Hokkaido on August 2. The full extent of the damage caused by the shock is not yet known, but more than a thousand fishing boats were damaged by a huge wave which followed the earthquake, seeming to point to an off-shore epicentre between Hokkaido Island and the mainland of the continent of Asia.

Announcements

Mr. R. C. Morrison, M.P., has been appointed chairman of an interdepartmental committee to secure greater liaison between the activities of the Ministry of Supply, which is responsible for the salvage campaign, and other services and departments.

The Adelaide meeting of the Australian and New Zealand Association for the Advancement of Science arranged for August has been postponed. The position will be reviewed when it is considered that conditions may be favourable for the holding of a meeting.

Awards are made from the Sir George Beilby Memorial Fund at intervals determined by the administrators, representing the Institute of Chemistry, the Society of Chemical Industry, and the Institute of Metals. Preference is given to investigations relating to the special interests of Sir George Beilby, including problems connected with fuel economy, chemical engineering and metallurgy. In general, awards are not applicable to workers of established repute, but are granted as an encouragement to younger men who have done original independent work of exceptional merit over a period of years. The administrators of the Fund will be glad to have their attention directed to outstanding work of the nature indicated, not later than November 1. All communications should be addressed to the Convener, Sir George Beilby Memorial Fund, Institute of Chemistry, 30 Russell Square, London, W.C.1.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Mucolytic Activity of Diffusing Factor Preparations

Chain and Duthie[1] have observed that aqueous testicular extracts contain a mucinase which rapidly reduces the viscosity of synovial fluid and causes an increase in the reducing power of this material. They suggested that the diffusing factor in testicular extracts might be identical with this mucinase and that the spreading effect in the skin might be due to rapid hydrolysis of interfibrillar mucin. This at first sight attractive hypothesis has been accepted by several workers[2,3,4], although no evidence has been advanced of the identity of the two effects, other than the known fact that snake venoms and bacterial filtrates, both well-known sources of diffusing factors, also show mucolytic activity.

Recent improvements in the biological test for diffusing factors[5] and an accurate viscosimetric method for the assay of mucolytic activity[6] have made it possible to compare the degree of activity shown by the various diffusing factor preparations when assayed by both methods. Dry preparations from bull testicle and rattlesnake venom were used and some results are given in the accompanying table.

Preparation	Diffusing potency (% standard)	Mucolytic activity (% standard)
Glaxo Laboratories standard (testicle)[5]	100	100
Madinaveitia standard (testicle)[7] ..	68	24·6
Dialysed extract (testicle)	48	80
$(NH_4)_2SO_4$ purified extract (testicle)	58	149
Crude *Crotalus atrox* venom ..	5·35	18·4
Purified *Crotalus atrox* mucinase ..	4·9	61·1

While these results are only of a preliminary nature we feel that they are sufficiently clear to warrant publication at this stage. It seems that there is no parallel between diffusing factor potency and mucolytic activity in the materials examined. Moreover, Meyer and his colleagues have recently encountered a similar absence of correlation[8]. While it cannot be said that diffusing factors are therefore not in some way related to mucinases, it seems certain that the method of assaying diffusing factors by merely measuring their mucolytic activity is open to grave objection. The possibility of a complete separation of diffusing factor from mucinase is the subject of investigations now in progress.

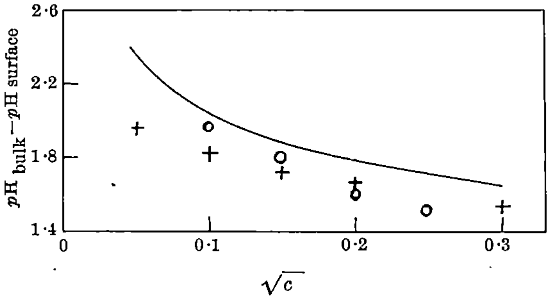
Concentration of Cations at Negatively Charged Surfaces

WHEN ions of one sign are fixed at a surface, the concentration of ions of the opposite sign in the surface phase may be calculated from the Gibbs-Donnan equilibrium between the surface and bulk phases[1], or from the electrokinetic potential. By both methods it is predicted that the pH at a surface containing fixed anions will be less than in the bulk phase, and Hartley and Roe have shown[2] that the pH at the surface of cetyl sulphate micelles, as calculated from the ζ potential (circles of accompanying figure) is in reasonable agreement with the values observed using a surface colorimetric indicator (crosses of accompanying figure). We have now calculated the pH at the same surface from the Gibbs-Donnan equilibrium (continuous line of accompanying figure) and find values in reasonable agreement with those obtained by the other two methods. The thickness of the surface phase was taken as that given by the theory of Debye and Hückel.



Wilbrandt has suggested[3] that the Gibbs-Donnan equilibrium can also be used to calculate the distribution of Na+ and Ca++ between a surface and a bulk phase. We have studied this by chemical analysis of palmitate monolayers spread on solutions containing varying concentrations of Na+ and Ca++. As predicted by the Gibbs-Donnan relationship, there is a lower Na : Ca ratio in the surface than in bulk, but the ratio found is much less than the predicted value (see accompanying table), which suggests that Ca++ may be bound at the interface by other forces in addition to that of simple electrostatic attraction.

MOLAR RATIO NA : CA IN MONOLAYERS OF PALMITATE SPREAD ON 0·1 *N* SALINE.

Ratio in saline	100 : 1	200 : 1	400 : 1	2000 : 1
Ratio found in monolayer	0·13 : 1	0·18 : 1	0·27 : 1	0·31 : 1
Ratio calculated from Gibbs-Donnan equation	4·5 : 1	8·2 : 1	15·5 : 1	109 : 1

The negatively charged surfaces act as reservoirs of divalent ions, and the discharge or dissolution of these surfaces will release a disproportionate amount of divalent ions. Such reservoirs may be the source of the intracellular free calcium released by stimulated cells[4].

Cosmic Rays and Poisson's Law

LET us consider a great number n of events of a sequence the mean value of which is $\bar{n}$. If these events obey Poisson's law, the probability of actual realization of the nth event is

$$P(n) = \frac{\bar{n}^n}{n!} e^{-\bar{n}}$$

In the case of cosmic rays, $\bar{n}$ would be the mean value of the number of cosmic rays registered during the same interval of time by a counter during a long interval, and n any number of rays registered in one interval by the same counter, the probability $P(n)$ of which is to be ascertained.

But Poisson's formula can be applied only if: (1) the probability of the event considered is very small (less than 0·1); (2) the frequency is never less than 10; (3) the events considered are independent.

The two first conditions are certainly fulfilled by the numbers of cosmic rays, the second one depending on the time of computation only. Therefore we shall deal with the third condition, which is essential. Indeed, it often occurs that a slight dependence entails extensive modification in the theoretical distribution based on the independence.

We tried to show the independence of the numbers of cosmic rays registered during the same interval of time, which was a quarter of a minute. The following method[1] was adopted. The registered values were grouped in three series: 'chronological series' (sequence of values as obtained); 'ordinal series' (sequence of values classified in increasing order); and 'series of consecutive values' (sequence of values which follows each observed value). Each of the two latter series is decomposed into decils, that is, into ten equal parts, numbered from 1 to 10, and from I to X. The probability that one value taken at random in the chronological series should belong to either decil of either group must be 1 : 10. Consequently, if there is independence, the probability that the same value should belong at the same time to two decils, one in the 1–10 group, the other in the I–X group, should be 1 : 100.

We had 1,600 numbers registered. Therefore, should we have each number with two indexes, one taken from the 1–10 group and the other from the I–X group, the result would be 100 groups of values, allowing for Bernoullian fluctuation $\mu^2 = npq = 16$. We arranged the following table:

	I	II	III	IV	V	VI	VII	VIII	IX	X
1	24	13	18	17	12	21	16	10	13	16
2	22	21	22	8	22	11	17	14	14	9
3	15	10	24	18	19	18	8	21	17	9
4	19	11	13	28	4	17	25	14	11	18
5	6	19	19	9	34	11	6	19	14	23
6	20	19	11	18	5	28	11	12	17	18
7	16	9	12	16	9	20	22	17	20	18
8	13	21	10	13	25	12	16	16	19	15
9	12	20	18	8	22	9	19	19	16	17
10	12	17	13	25	7	12	20	18	19	17

The table shows that 53 values are outside the theoretical limit 16 ± 3. The difference is of the same order of magnitude as the one M. Ferber found for the intervals between the emissions of the alpha particles of polonium[2].

The experimental proof of the hypothesis of independence has not therefore been obtained; and it seems that there is a correlation which, though feeble, renders doubtful the legitimacy of application of Poisson's law to the registered numbers of cosmic rays. On the other hand, the existence of four hyponormal groups (5–VI, VII), (6–VII, VIII), (7–II, III), (10–V, VI) confirms our conclusions, as according to the hypothesis of independence only one of these groups was to be expected.

Finally, the high values in the squares of the main diagonal of the table suggest the existence of many pairs of consecutive values of the same order of magnitude.

I am indebted to Prof. A. Cyrillo Soares for much valuable advice and assistance, and to the Instituto para a Alta Cultura for material support.

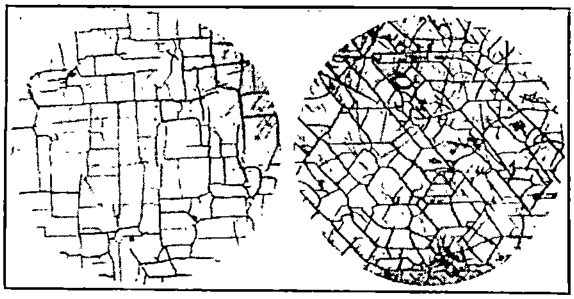
Etching Reagent for Chromite

THE resistant nature of chromite to all the usual etching reagents used in polished section examination is well known. Etch patterns on chromite would assist in the determination of the orientation of interlocking and anhedral grains in a rock and in the recognition of zoning. A search for a suitable reagent has revealed that chromite can be etched by treatment with concentrated perchloric acid, which is not mentioned in standard works on mineragraphy.

Polished sections approximately 2 cm. square were prepared on a billiard cloth lap or on a Graton-Vanderwilt polishing machine. The former method gives a satisfactory polish with most chromite specimens and is preferred, as it is necessary, before etching, to remove the bakelite mount used in the latter method.

The polished section is placed face downwards in a crucible of a size such that the specimen does not quite rest on the bottom. Sufficient perchloric acid to immerse the lower part of the specimen is added. For the size of specimen used, a No. 0 Royal Worcester porcelain crucible and 2–3 ml. of 70 per cent perchloric acid are satisfactory. The crucible is heated until the acid begins to fume, and the temperature is maintained until all the acid has evaporated. It is desirable to continue heating for about five minutes longer.



ETCHED CHROMITE: LEFT, CUBE FACE; RIGHT, OCTAHEDRAL FACE. × 400.

A first treatment may reveal no etching effects, and the procedure may have to be repeated several times. The depth and width of the etch grooves seem to depend to some extent on the short period of heating after the acid has evaporated, and great care must be taken to avoid disintegration of the polished surface by prolonging this final stage.

The perchloric acid often affects the cementing minerals and causes the polished surface to become extremely fragile. Parts of a section may fall out and etched specimens require gentle pressure when being cleaned. While chromite rocks with but little interstitial silicate minerals are not greatly weakened, those containing much gangue become rather more difficult to treat; nevertheless, even if only a few isolated chromite grains remain in the section, they can afford such data as may be required.

Polished surfaces parallel to the cube, octahedral and rhombic-dodecahedral faces of a large chromite crystal were prepared. The first-named face etched more slowly than the latter two. Cube and octahedral etch patterns are shown in the accompanying illustration.

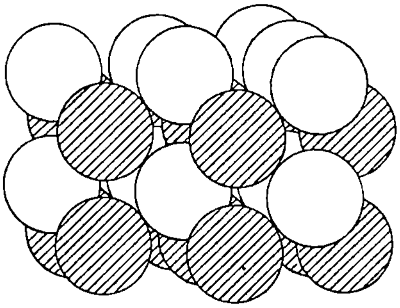
Symmetrical Arrangement of Equal Spheres

IN Barlow's paper[1] on the "Probable Nature of the Internal Symmetry of Crystals" he writes: "A fifth kind of symmetry . . . bears the same relation to the fourth kind as the second bears to the third; that is to say, it may be regarded as produced by the insertion of additional points in positions midway between points arranged in the fourth kind of symmetry". This is not so. Barlow did not describe or figure that arrangement which does bear the same relation to the fourth kind which the second bears to the third. It is shown in the accompanying figure. Its triangular base and first two layers are the same as those of Barlow's "second kind of symmetry"; but its third layer lies over the first, the fourth over the second, and so on. If now we insert additional points in positions midway between points in this structure, Barlow's "fifth kind of symmetry" is produced.



The new structure may be regarded as derived from the hexagonal close-packed assemblage by vertical compression and simultaneous dilation in horizontal directions. Similarly, compression of the cubic close-packed assemblage gives rise to Barlow's "second kind".

The elusive nature of the problem which Barlow set out to solve will be appreciated when it is recalled that P. G. Tait, examining the same subject, described two arrangements[2], supposed to be distinct, which are merely different aspects of the same thing (Barlow's cubic close-packed assemblage) and failed to discover the hexagonal close-packing.

Recombinants between Drosophila Species the F_1 Hybrids of which are Sterile

THE genetic analysis of species differences is of especial interest in precisely those cases where the sterility or inviability of the hybrids between the species stands in the way of such analysis. A notable case of this kind is that of *Drosophila melanogaster* and *simulans*, species which otherwise would present most favourable conditions for detailed analysis, on account of the already existing knowledge of the genetics of each species and the existence of abundant stocks providing suitable genetic tools ('markers'). We have found a means of circumventing the sterility of the F_1 hybrids between these species and thus obtaining types of the same kind as would be produced in a backcross of the F_1 hybrid, were it fertile, to *melanogaster*; it is at the same time possible to recognize, by means of the markers used, what combination of chromosomes is present in the pseudo-backcross progeny and thus to determine the effects of the different chromosome combinations.

The means used is to take triploid *melanogaster* females carrying recessive mutant genes in all their major chromosomes and to cross them with heavily irradiated *simulans* males bearing the dominant normal alleles of these genes. The triploid females produce eggs most of which have one or more of their chromosomes in diploid number. On the other hand the X-ray treatment, as we had found in earlier work with *melanogaster* alone[1,2], causes the loss of individual chromosomes, presumably by breakage, in some 5 per cent or more of the spermatozoa capable of giving viable offspring, although sperm in which two chromosomes have been simultaneously affected by a mutual translocation resulting in acentric and dicentric combination-chromosomes are incapable of giving viable offspring. When an egg with an extra chromosome or chromosomes happens to be fertilized by a sperm in which the homologous chromosome or chromosomes have been incapacitated, a viable diploid results, in which the chromosomes in question are of homozygous *melanogaster* type and the others are heterozygous as in the species hybrid. The kind of recessive character shown by the individual indicates which chromosomes are of homozygous *melanogaster* type. The resemblance to a backcross fails only in that the chromosomes are inherited as units; that is, there has been no opportunity for crossing-over.

Some 350 progeny have been obtained from this pseudo-backcross. The majority of the types of recombinants prove to be viable, although most have a viability considerably below normal. The inviability of hybrids bearing no *simulans X*, reported by Sturtevant[3] in 1920, proves to be due to interactions of genes in the *X* with those in both the second and third chromosomes, but more especially with the latter. Thus it has been possible to obtain viable adult hybrids without a *simulans X* but with a *simulans* II, and also (but not so readily) those without a *simulans X* but with a *simulans* III, when the other pair of major autosomes (III or II, respectively) is purely of *melanogaster* type. Study of the frequencies indicates the existence of several inter-chromosomal viability interactions. Similarly, it can be concluded that there are several interacting genes affecting fertility, as all viable recombinants of the major autosomes show sterility, although the degree of reduction of the gonad is (as shown by histological studies, carried out by Koller) different for the different chromosome combinations. The chief morphological abnormality of the hybrids—the bristle reduction and associated abnormality of the abdominal banding—proves to be due to interaction between a gene or genes in the *X* of *simulans* with an autosomal gene or genes of *melanogaster*, located at least in part in the second chromosome.

That the sterility and inviability effects are wholly chromosomal (and therefore Mendelian) in origin was shown by the obtaining of a single individual which happened to have all its major chromosomes from *melanogaster* and which alone, of all the progeny, proved to be fertile. The breeding of this individual to *melanogaster* has made it possible to transfer the fourth and the *Y* chromosomes into an otherwise purely *melanogaster* genotype. Here their *simulans* origin has been verified by cytological observations, carried out by Slizynski. Both chromosomes when in the *melanogaster* genotype show important genetic differences from their *melanogaster* homologues; a detailed analysis of these differences is in progress.

A full account of the above experiments and of the bearing of the results on problems of speciation is being prepared by us, and accounts of the histological and cytological observations will be published by Koller and by Slizynski, respectively.

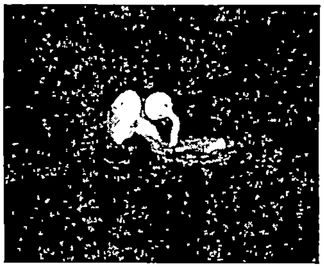
Blind Seed Disease of Rye-Grass

REFERENCE has been made by Wilson, Noble and Gray[1] to the confusion existing in the nomenclature of blind seed disease of rye-grass. The causal organism has been referred to by Hyde[2] as Pullularia, and the trouble is often referred to as "Pullularia disease". It seems doubtful whether the conidial form of the causal fungus is Pullularia, and the position is complicated by the occurrence of Pullularia sp. closely associated with the blind seed fungus. Wilson *et al.*[1] have pointed this out and state that the blind seed fungus and Pullularia sp. may be present on one and the same seed. Our work confirms this; both organisms may be found when examining seed samples. The conidia are distinct; those of Pullularia are smaller in size and yeast-like in character, while those of the blind seed fungus are larger, allantoid, and more regular in size and shape. Whereas Pullularia is usually associated with the glumes and the exterior of the caryopsis, the blind seed fungus only occurs in and on the caryopsis. Pullularia has been isolated from the caryopsis, but not from caryopses surface sterilized before examination. It is always the blind seed fungus which has been obtained in such cases.



DEAD RYE-GRASS SEED BEARING TWO OF THE HELOTIUM-LIKE APOTHECIA, THE PERFECT STAGE OF THE BLIND SEED FUNGUS.

Experiments designed partly to determine the relative pathogenicity of these fungi have been concluded and the results are of interest. Turves of commercial perennial rye-grass were lifted and brought to the laboratory. When in full flower, a bunch of the heads in each turf was inoculated with spore suspensions in sterile water. The following spore suspensions were used: (1) conidia of Pullularia sp. isolated in Northern Ireland from rye-grass seed; (2) conidia of the blind seed fungus isolated in Northern Ireland from rye-grass seed; (3) conidia of the blind seed fungus isolated by Neill in New Zealand; (4) suspension of ascospores from Helotium-like apothecia growing from dead rye-grass seeds in the rye-grass field from which the turves were taken. (These apothecia bear a marked similarity to those described by Neill and Hyde[3] in New Zealand; this appears to be a first record of their occurrence outside New Zealand, and a photograph of a dead seed bearing two apothecia is reproduced herewith); (5) control —heads immersed in sterile water.

Inoculations were made on June 4 and an examination for disease on June 24–25. Five hundred seeds were examined from each batch of heads. The young caryopses were extracted and examined microscopically for the presence of conidia. The following results were obtained.

The seeds from the control batch were all healthy. No conidia of either the blind seed fungus or Pullularia were found. No diseased seeds were found in the heads inoculated with Pullularia.

The heads inoculated with the Northern Ireland strain of the blind seed fungus showed 10·6 per cent of the seeds to be severely affected with the disease. At the time of examination, the diseased seeds were dull brown in colour, soft in texture and apparently quite dead.

Inoculation with the New Zealand strain of the parasite gave similar results; the percentage of diseased seeds obtained was somewhat lower, being 5·4.

The seeds examined from the heads inoculated with an ascospore suspension from the Helotium-like apothecia were affected to the extent of 7·6 per cent; the infection was typical. It would therefore seem clear that the Helotium-like apothecium found on dead rye-grass seeds in the early summer in Northern Ireland is the perfect form of the blind seed fungus. Cultures raised from single ascospores resemble those of the blind seed fungus in all respects.

Other apothecia resembling the type on rye-grass seed have been found on vegetable detritus, etc., in rye-grass fields. None has been tested for pathogenicity, but ascospores from them have not produced cultures similar to those of the blind seed fungus. Apothecia on the basal leaf sheaths of standing rye-grass have also been found, and it is believed that this form may be that referred to by Neill[3] as Lolium fungus No. 2.

These results show that the blind seed fungus is the parasite responsible for blind seed disease of rye-grass in Northern Ireland and, in the main, confirm the pioneer work carried out by Neill and Hyde in New Zealand. They also indicate that the Pullularia sp. commonly found associated with diseased rye-grass seeds is not parasitic, and that its role is probably saprophytic. It therefore seems desirable, for the present, to dissociate the name Pullularia from this disease, and to refer to it only by the name suggested by Neill, namely, blind seed disease.

Structure of *Hemimerus deceptus* Rehn, var. *ovatus*, and the Classification of Dermaptera

I have carried out detailed work on the external and internal anatomy of Hemimerus, and find that the semi-parasitic mode of life of the insect has modified various structures in its anatomy, but that it still retains many primitive features.

The mouth parts have bilobed lingula. There is a prostheca on the mandibles, and a large pair of superlinguæ. Pleural sclerites are well developed, despite the apterous condition, and the mechanism of hiding the legs under the body is interesting. There is a well-developed peritrophic membrane in the stomach, and a complex grinding mechanism in the proventriculus. The spiracular openings have a primitive guarding apparatus and (with one or two exceptions) there is an absence of transverse tracheal commissures. The most remarkable feature of the reproductive system is the presence of two ejaculatory ducts opening separately on a single penis.

Jordan[1] was not sure of this dual nature of the ductus ejaculatorius, while Snodgrass[2] mentions the presence of two exit ducts. Burr[3] thought that one of these ducts was reduced and had created two separate sub-orders, namely, Hemimerina and Arixenina, for the reception of Hemimerus and Arixenia respectively. The classification of Dermaptera could be simplified by dividing it into two series only, namely, Protodermaptera (with two ejaculatory ducts), and Eudermaptera (one ejaculatory duct). Hemimerus could be amalgamated into the former and Arixenia into the latter, while the two sub-orders Hemimerina and Arexenina be eliminated.

The insect was procured from Tanganyika, and as it differs from the specimens of Rehn[4], it has been named *Hemimerus deceptus* Rehn, var. *ovatus*, and specimens have been deposited in the British Museum (Natural History). The intersegmental membranes of many specimens were full of the hypopial stages of a Tyroglyphid mite. It is hoped that a detailed account of this work will shortly be published.

Colonel Kenneth Macleod

In the note on Colonel Macleod in Nature of July 20, p. 90, there is one omission which, I venture to think, should not go unremedied, namely, his description in 1881 of what he thought was a "new disease", in fact he called it the "New Indian Disease", allied to, but at the same time not identical with, beriberi; he gave it the name of "epidemic dropsy". He had observed it in Calcutta and its suburb Howrah from 1877 onwards. Though the etiology is even now not quite clear, Macleod's clinical description was so full and accurate that little has been added to it, and nothing has had to be taken away. This shows how great were his powers of accurate clinical observation.

A more detailed account of the condition is given in "A History of Tropical Medicine" (London: Edward Arnold, 1939), vol. 2, pp. 897 *et seq.*

RESEARCH ITEMS

Li Tribes of Hainan Island

A PRELIMINARY study of the origin of the Li tribes of Hainan Island by Chungshee H. Liu appears in the first issue (January 1940) of *Meridio-Occidentale Sinense*, a newly established journal for the scientific study of south-west China published by the South-West China Society at Kunming, China. The Li tribes are first mentioned in the "Annals of the Han Dynasties" (206 B.C.–A.D. 219), and since have been known by various cognate names, themselves adding a labial which by a phonetic change might suggest a relation with "Malay". In some localities *Moi* points to a common origin with other aboriginal tribes of Indo-China; or again an affinity with the Lao of Tonkin has been suggested. There is reason to believe that the present Li tribes are descended from the Lii family or clan; but whether they had settled in Hainan before the Han dynasty or came to the mainland through Hainan demands further research. Physically the Li are a fine race of stout or slender build and medium stature (160 cm.). The skin is yellowish-brown, red-brown, or pale yellow; hair black, straight and fine; eyes medium brown, rarely light brown, oval, semi-oval or round in aperture, the eyefold being absent, but rarely traceable; nose concave or straight with more or less flat apertures. The cheek-bones are not prominent. The cephalic index is 80·20, the nasal index 75·73. In all these characters they differ from the Chinese, but are akin to Tai (Shan) on the one hand and Malay on the other. There has been, however, a generous admixture of Chinese blood. Racially they may be classified as Oceanic or Southern Mongols or Nesiots, or as Palæomongolides of von Eichstedt's new classification. The cultural relationship is complicated, but they appear to belong to the Indonesian cultural cycle. Linguistically their language belongs to the Thaic family.

Nutritional Oedema and Dietary Deficiency

J. B. YOUMANS read a paper on this subject at the Eighth American Scientific Congress on May 14. Nutritional oedema, long ago described under such names as famine oedema and starvation oedema, has, since the War of 1914–18, been known to be due to a lowering of the serum proteins caused by a deficient intake or an improper absorption or utilization of food. The disease appears epidemically, endemically, or as sporadic cases. Epidemic and endemic cases occur in populations subsisting temporarily or permanently on inadequate diets, particularly diets low in protein. Sporadic cases occur in patients with other disease which affects the intake or absorption of food. The principal clinical manifestation of the disease is an oedema of varying degree with few other signs and symptoms in uncomplicated cases. Diagnosis is made by the presence of the oedema, otherwise unexplained, associated with a decrease in the concentration of serum proteins, and a drop in the colloid osmotic pressure of the blood. A determination of the serum proteins may reveal a latent or preclinical stage of the disease before the oedema becomes manifest. Observations on the incidence and manifestation of the disease in the southern part of the United States are to be reported.

Damaged Starch and the Diastatic Activity of Flour

THE shearing and crushing in the roller milling of flour results in a particular type of damage to starch granules characterized microscopically by a curious flat appearance and faint outline (C. R. Jones, *Cereal Chem.*, 17, 133; 1940). Their attenuated outline in contrast to the boldness of some granules has suggested the term 'ghosts'. Congo red does not stain sound granules of starch, whilst 'ghosts' all stain orange pink. In general, it is found that in flours differently milled from the same wheat the order of abundance of 'ghosts' is in the same direction as the 'maltose' figure. The enzymes responsible for the diastasis in sound non-germinated wheat may be regarded as uniformly distributed over the endosperm. The soluble 'inner starch' is ordinarily protected by an envelope or skin of insoluble 'outer starch' surrounding the granule. The former alone is fermentable by the diastatic agent, which cannot act until the outer resistant skin of the granule is broken, and the 'ghosts' alone are therefore the source of sugar formation in dough. Differences in diastatic activity between flours from different types of wheat are not necessarily due to differences in amylase content or in starch susceptibility; they are at least partly to be explained by differences in the physical hardness of the endosperm, this in turn determining the extent of the damage to the starch during milling.

Origin of the Loganberry

THERE has been considerable debate as to whether the loganberry is a hybrid between the Californian blackberry, *Rubus vitifolius*, and the raspberry, as claimed by its raiser, Judge Logan, or whether the loganberry is an offshoot of *R. vitifolius*. M. B. Crane (*J. Genetics*, 40, 129–140; 1940) and P. T. Thomas (*J. Genetics*, 40, 141–155; 1940) have produced considerable evidence to support the theory of hybrid origin. Crane crossed *R. vitifolius* with a tetraploid raspberry and obtained a hybrid which resembles the loganberry in morphology, sex, fertility, and chromosome number. It, like the loganberry, is nearly true breeding. The dominance relationships in these polyploids and sex determination in the Rubi hybrids are interesting. The cytology of *R. vitifolius*, loganberry and diploid and tetraploid raspberries indicates that the Hailshamberry and Everbearing are autotetraploid raspberries $iiii$, *R. vitifolius* is an allooctoploid $v_1v_1v_1v_1v_2v_2v_2v_2$. The hybrid between *R. vitifolius* and Hailshamberry has completely paired chromosomes and has the chromosome constitution $v_1v_1v_1v_1\,ii$, which is also believed to be that of the loganberry. Further cytological evidence indicates that the chromosome sets v_1v_2 and i are related to one another, but differentiation has taken place in the different species.

An Electromagnetic Microbarograph

To see whether microseisms might be caused by microbarographic oscillations of similar period, electromagnetic microbarographs have been set up at St. Louis and Florissant (*Trans. Amer. Geophys. Union*, 1938). The instruments were built by W. F. Sprengnether of St. Louis with the collaboration of D. C. Bradford and Father Vincent M. O'Flaherty. One consisted essentially of a large brass air chamber (*ca.* 18·3 litres), over the open end of which was tightly stretched and clamped a rubber diaphragm. The drum stood on its side so that the plane of the diaphragm was vertical. A short solenoid was attached to the diaphragm at its centre with its axis normal to the rubber surface and its weight supported from the frame by two vertical wires balanced by pairs of rubber stays below, spaced at angles of 120° each and stretched parallel to the diaphragm. Into the air core of the solenoid was inserted without contact one pole of a cobalt steel bar magnet rigidly supported by the frame. The air chamber was provided with an adjustable needle valve so that the pressure within the chamber slowly adjusted itself at any predetermined rate to the average atmospheric pressure outside. It was found that a Leeds and Northrup type *R* galvanometer of seven seconds period gave the best registration. The galvanometer magnified the membrane vibrations about 6,600 times. The galvanometer and microbarograph coil were shielded from stray fields. Odd recordings were found to be due to the instrument behaving as a seismograph for very short period vibrations. Blasts and nearby earthquakes have been recorded by the microbarograph when the vibrations of the ground had more or less the same period as the natural vibration of the membrane (*ca.* 0·1 sec.). Distant earthquakes do not affect the microbarograph. The instrument has worked extremely well.

Interior of the Earth

R. STONELEY has published a paper in which he gives a short summary of the various lines of research that supply information on the interior of the earth (*Occas. Notes Roy. Astro. Soc.*, No. 8 ; March 1940). Wiechert's hypothesis that meteorites may be typical of the matter, considered from the chemical point of view, of which the planets are composed, suggested from the classification of meteorites into stony and metallic that rock and iron would be the chief constituents of the earth. On these grounds he proposed a core of specific gravity 8·2 and of radius 0·78 times that of the earth, surrounded by a shell of which the material had a density 3·2. Observations of variation of latitude, earth tides and horizontal pendulums supply important evidence regarding the interior of the earth, and a brief explanation is given of the application of these methods. The well-known h and k terms in the equilibrium tide cannot be derived by observation from the yielding of the earth, but k can be derived from the observations of the variation of latitude. Knowing the value of $1 - h + k$, h can be found, and as these quantities can be obtained by an independent method on the assumption of a certain constitution of the earth, a comparison can be made. Sir George Darwin deduced in this way a rigidity for the earth comparable with steel, assuming a homogeneous composition. The greater portion of the paper is occupied with a description of the evidence obtained from earthquake records. The primary and secondary phases of the preliminary tremors, denoted by P and S, have been identified with the arrival of compressional and distortional waves that have passed through the body of the earth, the times of travel being approximately 1 to 1·8. The behaviour of these waves for epicentral distances greater than 105° led Oldham in 1906 to suggest that the earth had a core of small or zero rigidity incapable of transmitting distortional waves. The subsequent work of Knott, Gutenburg, Wiechert and Jeffreys on the nature of this central core is briefly dealt with. Among other matters considered in the paper are the electrical conductivity in the interior of the earth and the distribution of the internal temperature ; this attains about 3,000° C. at a depth of 550 km., according to Jeffreys.

Adsorption at a Liquid Interface

IT has been shown by experiment that the adsorption at a gas-liquid interface does not always agree with that calculated from Gibbs's equation $\Gamma = -c(d\sigma/dc)/RT$. C. W. Gibby and C. Argument (*J. Chem. Soc.*, 596 ; 1940) have measured the adsorptions of five dyes (methylene blue, Congo red, Bordeaux extra, indigo carmine X and Solway ultra blue B) at a mercury-water interface. The last two include types of structure (indigoid and anthraquinonoid) not previously studied. In each case it was found that the measured adsorption passes through a maximum as the dye concentration increases and is always positive in the concentration range examined. The areas of interface per molecule adsorbed were calculated, together with the approximate areas of the molecules. The ratios of the two sets of values suggest considerable orientation of the molecules at the interfaces. Interfacial tension measurements were made and from them values of the adsorption calculated by Gibbs's equation. These are not in agreement with the measured values and in some cases are negative. In no case do the curves representing theoretical and measured adsorptions coincide at small concentrations.

Use of Eros to determine the Solar Parallax

THE Astronomer Royal has discussed the programme of observations of Eros near the favourable opposition of 1931 (*Mon. Not. Roy. Astro. Soc.*, **100**, 6 ; April 1940). Observations made at Bergedorf Observatory published recently by Dr. C. Vick (*Ast. Abh. Hamburger Sternwarte in Bergedorf*, **5**, No. 3, 1939) led him to conclude that Eros is unsuitable for the accurate determination of the solar parallax. Vick's conclusions are not corrobated by Dr. Spencer Jones. The short-period variations with periods 12·5311 minutes and 79·6845 minutes found by Vick are shown to be non-existent, and the explanation of the large probable errors of some of the Bergedorf observations is found in the unsatisfactory method of observation. Although these suspected short-period variations in the position of the centre of brightness of Eros are not confirmed, other apparent variations in position of the centroid of brightness with periods 5h. 16m. and 2h. 38m. are next investigated. Eros is known to be variable in brightness with a total period of 5h. 16m., and the period between consecutive minima of brightness is 2h. 38m. In the discussion of the 1901 observations, Hinks did not obtain conclusive evidence of such variations, from which it may be inferred that the effect must be small. The present investigation failed to detect any variation with period 5h. 16m., nor could any variation with period 2h. 38m. be detected in right ascensions. There is a small but well-confirmed displacement in declination with a period 2h. 38m., of total range about 0·05″. As this variation has no systematic effect on the determination of the solar parallax from the comparison between the observations in declination at northern and southern observatories, the conclusion is that Eros is a suitable object for the accurate determination of the solar parallax.

SOME ASPECTS OF AMERICAN CONSERVATION SCHEMES*

ROLE OF RECLAMATION IN CONSERVATION

BY JOHN C. PAGE, BUREAU OF RECLAMATION

THE biggest job for conservationists is to combat the habit of thinking in terms of limitless resources. The destructive results of this habit, seen in our dwindling forests, our abandoned mines, and our gullied fields, have not yet caused sufficient impression to turn us completely away from our foolish optimism as to the future.

The movement towards conservation, begun under Theodore Roosevelt four decades ago with the establishment of the National Forest Service and the Bureau of Reclamation, has received its greatest impetus under President Franklin Roosevelt. Mr. Harold L. Ickes, of the Department of the Interior, defines conservation as 'prudent use'. This is the sense of the word in which the Bureau of Reclamation has tried to carry forward its own particular field of conservation—irrigation in the West. One third of the United States—the West—is arid or semi-arid. Much of this third is desert. Streams periodically drop to tricklets in the dry summer. No agriculture is safe in this West without irrigation, and even irrigation is unsafe without storage reservoirs.

Irrigation in the West is old, was practised before the coming of white men, who took up and improved on Indian methods and thus founded their first settlements. Now twenty million acres have been brought under irrigation, through individual enterprise, co-operative endeavour, and State and Federal aid. Increasing size and complexity of irrigation works have thrust the Federal Government into the position of being the principal agent in the field of water conservation and desert land improvement.

Beneficiaries of this work, carried out by the Bureau of Reclamation, pay its cost. Out of concession to national benefits, the irrigators are not charged interest, but other beneficiaries, such as consumers of electric power, are.

The carefully thought-out conservation work of the Bureau of Reclamation contrasts with earlier methods of developing the West, to which part of our present difficulties are directly traceable. Once western land was regarded as merely a source of revenue. Later, 160 acres was arbitrarily selected as the proper homestead for a family. Still later, it was recognized that irrigation alone would provide the necessary security in most western areas.

With the exception of the Bureau of Reclamation, which plans conservation controls on water and land in advance of their use and development, conservation activity to-day is mainly corrective. The constructive work of the Bureau has resulted in 53,000 new farms, 258 new cities and towns where nearly 1,000,000 people live.

One fifth of the cost of Federal Reclamation projects has been repaid. The projects turn 100,000,000 dollars yearly into the channels of trade. The present programme will ultimately provide 850,000 people with homes.

The future of reclamation is limited by the West's water supply. Its horizon is placed at 42½ million acres, about 6½ per cent of the 700,000,000 arid and semi-arid acres in the West. Twenty million are already under irrigation, and 2½ million are in the Bureau's present construction programme, leaving but 20 million available.

CONSERVATION OF FOREST RESOURCES

BY C. L. FORSLING, U.S. FOREST SERVICE

Forests in great variety originally covered 7½ million square miles, or one half of the land surface of the Western Hemisphere. The area has been reduced to about 6 million square miles since the beginning of the sixteenth century. Growth of population and industries since the middle of the nineteenth century resulted in serious inroads into this rich heritage, especially in the United States, where the deliberate policy of the Government was to transfer ownership of the natural resources into private hands.

The forests of the United States and Canada, owing to their composition and the character of their principal woods, were cut heavily to supply world markets and to meet the needs of growing local populations. Extensive devastation and severe deterioration of the remaining forests resulted. A major problem now is the rehabilitation of these forests to restore them more nearly to their potential continuous productive capacity, which, for the most part, will be a slow process. Meanwhile, demands on the forests of the other American countries will probably increase. Unless steps are taken to prevent it, exploitation of these forests is likely to result in unnecessary destruction or impairment of their productivity, with economic and social effects at least as disastrous as in North America.

The experience of the United States suggests the following essential foundations for a sound policy of forest conservation and use:

(1) Systematic land-use planning to determine, in relation to other forms of land use and social and economic requirements, the amount and character of the available land resource that should be devoted to forestry.

(2) The formulation of policy as to the kind and extent of forest land that should be in public ownership and under public management.

(3) The determination of the means whereby the public may aid in keeping privately owned forest lands productive, and of the degree of public control needed to be exercised over privately owned forest land in order to safeguard the public interest in these resources.

(4) Broad education of people in general and forest owners in particular, as to the value of forests and the basic principles of a forest policy.

(5) A broader knowledge of suitable technique for harvesting and processing forest products, in order to minimize waste, enable efficient operation, and bring the highest sustained income in the long run.

---

* From papers presented at the Eighth American Scientific Congress meeting at Washington during May 1940.

(6) A broader knowledge of the science and practice of forest management and the underlying sciences, with adequate provision for research in these and related subjects, including better protection from fire, insects, and disease.

(7) Development of uses and markets for all manner of forest products, including research on the properties and utilization of wood and other forest products.

(8) Competent, adequately trained forestry personnel.

(9) A minimum of political interference with forestry personnel and policies.

Co-operation of all American countries is needed in order to advance the science and practice of forestry in the Americas; a Pan-American forestry institute is suggested for this purpose.

NATIONAL PARKS IN CONSERVATION

BY ARNO B. CAMMERER, DIRECTOR, NATIONAL PARK SERVICE

The national park idea originated in the New World. In 1870, a party exploring the Yellowstone decided not to try to claim parts of the area for private exploitation but to work for its preservation as a national park to be preserved and enjoyed by the public for all time. Yellowstone, established in 1872, was, therefore, the first national park.

In 1906, the Antiquities Act recognized archæological material on public lands as public property and authorized the President to establish publicly-owned objects of prehistoric, historic, and scientific interest as national monuments, to be preserved intact. In 1916, Congress established the National Park Service to protect the national parks, monuments and similar recreational reservations and to promote their appropriate public use.

In 1933, all national parks, monuments and related historic sites were brought together under the jurisdiction of the National Park Service. In 1935, the Historic Sites Act enunciated the national policy to preserve historic sites and objects for public inspiration and benefit. In 1936, Congress authorized the National Park Service, in co-operation with other Federal agencies and with the States, to conduct a national recreational area study for the purpose of providing a co-ordinated national recreational programme.

The national park system now includes 158 historic and natural areas, totalling 21,515,000 acres. Recreational utility is the yardstick of good land management. Parks are a form of land use—not a type of scenery. The park type of use is equally applicable to the mountain tops, the great plains, the coastal forests, the deserts, or the seashores. Park standards refer to the type of reservation and not to the type of scenery included in it. In parks we attempt to preserve the land whole. To do so our management must rest upon a sound, scientific basis. Parks are for people to use, but we should not confuse the purposes of the wilderness park with the purposes of the city park. Each has its legitimate purposes and should be developed to achieve those purposes.

How many parks are needed? The answer cannot be given quantitatively because recreation is a quality of living. There would be more parks if it were not for the vain promises of the multiple use advocates. Multiple use is the theory that lands can be most profitably managed if used in a number of different ways simultaneously. Multiplicity, however, is not and cannot be an objective. Parks and recreational areas may provide multiple use, but multiplicity is merely an incidental phase of good land management. Multiple use as a descriptive term is not objectionable provided it is merely descriptive of that which is an incidental aspect of optimum use. The multiple use theory has been confused with sound land classification. It is believed that the exponents of multiple use really have optimum use in mind. The classification of resources for their best use would result in more adequate recognition of park and recreational lands.

RANGE CONSERVATION

BY R. H. RUTLEDGE, DIRECTOR, GRAZING SERVICE

In the aftermath of the War of 1914-18, expansion followed by drought, depression, dust storms and shifting populations, America began seriously to take stock of her natural resources. The inventory revealed that a sizable part of our economic and social problems were traceable to a dwindling of range resources. Among other things the evidence led to the conclusion that to ensure the foundation for a desirable standard of living in the range country and in the nation generally there must be an adequate area of forage-producing land and a range conservation programme designed to foster its continued productivity. To secure such a programme Congress passed a number of conservation Acts and placed the conduct and co-ordination of that programme in several Federal agencies. Through the guidance of the Federal Government and the co-operation of States and the citizens range conservation is going forward on a wide front.

The Western range country comprises about half of the total area of the United States. It consists of 11 far-western States and sizable portions of the 6 adjacent plains States. Its gross area of about 1,525,000 square miles is slightly greater than the total of Bolivia, Chile, Colombia and Ecuador, and its grazable land, containing about 1,137,000 square miles, is comparable to the area of the Argentine.

Three-fourths of the wool and mohair, half of the lamb and mutton and nearly one third of the beef and veal consumed in the United States is produced in the western range area. Nearly half of the land is in private ownership; the remainder is public land belonging to States, counties and the Federal Government. Collectively these lands comprise the nation's most important watersheds, and within their borders are found practically all of this country's irrigation projects.

Practically all the development and settlement of this vast area has occurred within the past seventy-five years. In a growing nation possessing seemingly unlimited resources there was no guidance, no general plan to assist the citizens in its development. It was inevitable, therefore, that under existing trial and error methods many mistakes occurred. In this area of variable climate, precipitation, altitude and soil texture there is a delicate balance between plant growth and these factors. There is likewise a delicate balance between plant growth and factors of land use.

Livestock numbers are limited to the safe carrying capacity of the land by the issue of licences and permits to resident users of the range. Studies are made to determine proper seasons of range use, the class or classes of livestock that can use the range most beneficially, and the feasibility of withdrawing from use certain areas to effect rehabilitation by both artificial and natural means.

The problem of range management involves a study of the relationship between private and public land and the devising of plans to make the use of all the lands compatible with the available resources and the economic structure. Range improvements consisting of water development, re-seeding, erosion control works, trails and other facilities, and the elimination of undesirable elements such as rodents, predators and poisonous plants are included in the programme.

Units to facilitate particular administrative objectives and to localize problems in conformity with community and region welfare assure a broad attack on social and economic, as well as physical fronts. By this means the programme is enabled to outline and develop a type of land use that, in the end, will ensure the stability of the unit involved. In turn, this unit, whether it be a grazing district, a national forest, an Indian reservation, a game range, or any suitable allotment or portion thereof, will reflect the benefits derived on the public welfare generally.

LAND UTILIZATION AND FISH CONSERVATION

BY ELMER HIGGINS, BUREAU OF FISHERIES

Land utilization and water utilization are closely related. Water utilization affects aquatic life through changes in habitat. No other group of vertebrates is so delicately adjusted to environment as are fishes. Sudden changes in the nature of environment afford the fishes no opportunity to escape, and death is the only alternative.

Land uses and abuses that have contributed to the diminution of our resources in fresh-water and anadromous fishes, including the effects of agriculture and lumbering, mining operations, petroleum extraction, manufacturing, and the development of urban life and recreational areas are all important. Land restoration practices that do not conserve fish-life include irrigation, power development, canalization of streams, and the draining of sub-marginal lands. Land restoration practices that aid in fish conservation or can be adapted to conservation objectives include erosion control, flood control, pollution abatement, and properly designed water impoundments.

The diversity of interests in land and water utilization demands the development of a co-ordinated conservation programme, particularly with respect to water conservation. The objectives of such a programme may be summed up as follows: The adoption of general principles of water conservation will aid in fishery conservation if the requirements of aquatic life are taken into account when water utilization projects are being planned. In general, the water should be kept on the land, rapid run-off retarded, flood waters stored, erosion prevented, pollution prohibited, canalization of streams minimized, irrigation canals screened, impoundments operated with minimum fluctuation of water-level, dams constructed with outlets at base to improve circulation in reservoirs and provided with fishways where important runs of fishes are obstructed.

SOCIAL STATISTICS OF MERSEYSIDE

THE "New Handbook of Social Statistics relating to Merseyside" prepared by the Statistics Division, Social Science Department, the University of Liverpool (University Press of Liverpool, 1940. 1*s*. net), gives a statistical statement of the position on Merseyside in relation to trade, employment and other social conditions immediately before the outbreak of war. The sections on elementary education and housing have been omitted and rather more material is included relating to the changing state of employment. The first section on the trend of births, deaths and population directs attention to the continuous and steep fall in the birth-rate until the last few years, the level reached in 1938 being about two thirds of that recorded in the 1911–15 quinquennium. The trends of the general death-rate and infant mortality-rate show no evidence of great scope for a further reduction of the general death-rate, and infant mortality is unlikely to decline at the rate experienced in the earlier years of the century. In each of the four boroughs there appears to have been a more or less stable position by 1938, with even a slight tendency to a natural increase in population.

Figures given for the trade of the Port of Liverpool in comparison with that of London, Hull, Southampton and Manchester show that between 1932 and 1938 import values rose by 30 per cent in both London and Liverpool, while export values increased by 50 per cent in London but only by 24 per cent in Liverpool. Articles wholly or mainly manufactured account for £120 millions out of £139 millions exported from Liverpool in 1938, but represent only about one eighth of the goods entering Liverpool. In regard to imports of foods, certain foods touched their lowest point in 1935–37, afterwards rising to about two thirds of their value in 1927–29, whereas the value of every imported raw material listed was higher in 1935–37 than in 1930–32, generally receding again slightly in 1938.

Since 1927–29, the number of insured persons on Merseyside has increased from 362,000 to 424,000, while the number of unemployed rose from 57,000 in 1930 to the 100,000 level in 1935, declining to 80,000 by the middle of 1939. The tables indicate a decline in shipping and shipbuilding over the last ten years and in transport and distribution since 1932, with expansion in metals and engineering and in general service. Shipping and shipbuilding, transport and distribution, now account for only 41 per cent of the total of insured workers as against one half ten years ago. General service, however, has increased from 12 per cent in 1929 to nearly 18 per cent. Taking all industries, the number of insured workers employed in 1939 was 12 per cent above the 1929 level on Merseyside and 18 per cent above that level in the country as a whole. With regard to unemployment, while in comparison with 1932 all industrial groups show decreases in the percentage of insured workers unemployed, varying from 22 in transport and distribution to 67 in metals and engineering, Merseyside shortly before the War had still a percentage of unemployment of 18·8 as against 9·6 in Great Britain and Northern Ireland as a whole.

Analysis of the unemployment situation indicates that out of nearly 80,000 unemployed, 35,000 may be regarded as normal, 8,400 must be attributed to the abnormal times from which all parts of the country have suffered, and 36,000 to the exceptional character of Merseyside. One half of the normal unemployment on Merseyside is accounted for by the shipping, shipbuilding and related industries, where a high proportion of the total is made up of dockers and other casual workers. The general rise in unemployment among women since February 1939, while unemployment generally had decreased by nearly 24,000 (February 1940), is attributed to the much greater transfer of men to the heavy industries and to other war-time production and to the services. The number of unemployed clerks, typists and bookkeepers increased from 592 in 1939 to 2,731 in 1940, due to the closing down or contraction of businesses engaged in the manufacture or distribution of commodities not essential for life and a moderate degree of comfort and for the prosecution of the War. Unemployed boys between 14 and 17 years of age decreased by 22 per cent and girls by 5 per cent when the average of 1939 is compared with 1938, while for boys the February 1940 figure was 18 per cent better than the February 1939 figure, the March figure being 39 per cent better than last year's. For girls the February unemployed total was 57 per cent greater than the 1939 figure, but for March 1940 the figure was only 34 per cent greater than that of March 1939.

For the combined unemployment benefit and unemployment allowances, the expenditure during four weeks in 1939 was £387,544 as against £280,530 in the corresponding weeks in 1940. The total number of persons in receipt of relief in the combined Merseyside boroughs fell from 58,000 in March 1939 to 48,000 in March 1940, with a decline in expenditure from £75,689 to £71,441 for the corresponding four weeks. The local rates have been increased only slightly for 1940–41, increases due to civil defence measures being offset to some extent by savings under 'black-out' regulations.

FISHERIES RESEARCH IN HONG KONG*

IT does not often happen that the official publication of a research station makes its appearance before the erection of the station itself has even begun; and certainly this enterprising inauguration of the *Journal of the Hong Kong Fisheries Research Station* will be most gratifying to those who have persistently advocated and worked for the establishment of fishery science throughout the British Empire. Tribute will be paid to Dr. Herklots, the editor of the *Journal* and honorary director of the Station, whose organizing ability and unbounded enthusiasm inspire confidence in the future of the work at Hong Kong, despite the tremendous difficulties occasioned by wars to which both the British and Chinese peoples are unhappily committed.

Since the primary purpose of the Station is to study the fishes of the South China seas and the fishing techniques employed by the local fishermen with a view to the future benefit of the fishing industry, it is appropriate that the early numbers of the *Journal* should be devoted to a general survey of the Hong Kong fisheries. Dr. Lin makes a good beginning with his detailed and well-illustrated account of the boats, gear and fishing methods. It is the story of a remarkable people who make their permanent homes and live their lives in the fishing junks with their families. Men and women, and girls and boys above the age of fifteen, form the fishing personnel; family life proceeds in specified quarters; and a shrine for worship is always to be found in the heart of the ship.

The junk trawlers, varying from 50 to 90 feet in length, are perhaps the biggest and most important fishing vessels employed in China. It is claimed that there are about a thousand registered in Hong Kong, all operated and many owned by the floating population of Kwangtung and Hong Kong. Save for the smaller forms, all the trawling junks are three-masted wooden vessels with the bow comparatively low and the stern very high. No wheel house is provided and the detachable, heavy rudder is manipulated by means of the tiller on the high stern. Sleeping places for the crew are located below deck in front of, or behind, the main mast; the shrine is always situated in a hold immediately in front of the aft hold. On the stern, several rooms are constructed above the poop to accommodate the owner's family and the galley. Drinking water is kept in holds either on both sides of the main mast or behind it. The fishing gear, ice, salt and the catches are stored in special holds between the main mast and the stern. A long roller for hauling in the trawl is fitted with 8–10 handles and operated by 8–10 members of the crew, and is situated either on the starboard side behind the main mast or transversely in front of it. The anchors are manipulated by capstan. The sails are constructed of mats in preference to canvas; the latter is the better material for sail-making but is too light to be easily lowered or swung from one side to the other with the speed required during fishing operations.

Giving equally interesting details, Dr. Lin goes on to describe beam-trawlers, purse-seine and drag-seine junks, and long-liners. Next he deals with the personnel, varying from 6 to 25 persons per junk, most of whom are hired on a time-wage basis with (sometimes) a bonus on the value of the catch. As most of the fishermen know the whole process of fishing and the different tasks on board are sufficiently straightforward, there is no special allotment of duties, and all interchange freely. Eight types of fishing gear are used, all of which should be of particular interest to students of British fisheries, since there is much to be learned from them which might well prove serviceable in home waters. E. F.

CAST IRONS IN AUTOMOBILE CONSTRUCTION

DURING the last ten years the progress made in automobile development and production has been due, in very large measure, to improvements in the materials of construction. Of these, cast iron ranks as one of the most important. The great majority of the cars currently purchased in the United Kingdom are of the 'quantity production' class. It is the use of this type of car that is considered by E. C. Toghill and R. V. Dowle in a paper on the "Applications of Cast Iron in Modern Automobile Construction" recently published (*J. Inst. Automobile Eng.*, March 1940).

The object of the paper is to bring to the notice of the automobile engineer and designer some of the irons with special properties for specific applications, and to show that the grading of cast iron and the choice of the correct grade for the purpose are as important as in the case of steels.

The influence of nickel, chromium, molybdenum and copper in cast iron is summarized as follows. In connexion with the use of special elements, the important role of nickel in automobile cast irons is pointed out. Nickel is a graphitizing element, being in this respect about one third as powerful as silicon, but whereas silicon coarsens the grain and the graphite, nickel has a refining effect. In addition, the presence of the nickel renders the iron more uniform and less sensitive to sectional change. A correct balance of nickel and silicon is an important factor in the production of an alloy having the best properties. For example, if no allowance is made for the graphitizing influence of nickel, that is, if no proportionate reduction of the silicon is made, little increase in strength is observed up to about 1·5 per cent of nickel, after which, strength and hardness gradually increase. If, on the other hand, the silicon content is suitably adjusted, additions of 0·5–5 per cent of nickel will give 10–50 per cent increase in tensile strength.

Strength, hardness, depth of chill, and resistance to heat wear and corrosion are increased by the presence of suitable amounts of chromium, and provided that the carbide is not in massive condition, the shock-resisting ability of the iron is also enhanced.

Molybdenum refines the grain of the iron and the graphite, and has a very beneficial effect on shock resistance. Molybdenum stabilizes carbides and increases tensile and transverse strength; it also produces a slight improvement in corrosion- and heat-resistance and in machinability. In many respects, copper produces similar effects to nickel. Tensile and transverse strength are improved by the presence of small amounts of copper, the effect being most pronounced in low carbon irons. Fluidity of cast iron is also improved by the presence of copper.

Messrs. Toghill and Dowle direct attention to the extensive research in progress under the joint auspices of the Institution of Mechanical Engineers and the British Cast Iron Research Association, in which a collation is being made of the range of high-duty cast irons and of their properties and uses in general engineering. The aim of the work is to provide the automobile and other engineering industries with data which will facilitate the choice of the grades of cast iron suitable for widely diverse applications.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

GRADUATE IN PURE SCIENCE able to take CHEMISTRY, PHYSICS and MATHEMATICS TO 1ST YEAR DEGREE STANDARD, and a WORKSHOP INSTRUCTOR also capable of taking some MACHINE DRAWING—The Principal, County Technical College, Worksop, Notts (August 15).

CHIEF ASSISTANT ENGINEER to the Port of Bristol Authority—The General Manager, Docks Office, Queen Square, Bristol 1 (August 19).

CHIEF LABORATORY ASSISTANT in the County Bacteriological and Pathological Laboratories—Dr. T. N. V. Potts, County Medical Officer, County Hall, Wakefield (August 19).

EDUCATIONAL PSYCHOLOGIST—The Director of Education, Education Department, Town Hall, Barnsley (August 21).

PREPARING FOR A NEW WORLD ORDER

THE rapidity with which the march of events has thrown on Great Britain the main and almost the sole burden of the defence of the liberties and traditions of Western civilization, endows with something of prophetic vision the Prime Minister's declaration on June 4 of our determination to continue the struggle : "if necessary, for years, if necessary, alone". Under that burden we can have but one war aim—victory. Inexorably other discussion on war aims has for the time being to be thrust into the background, like the shattered solemn declaration of the Supreme War Council of March 28, with all the hopes it seemed to foreshadow of a new European order based on Anglo-French co-operation.

Such co-operation is for the time being impossible. On us now falls the material burden of staying the onslaught of aggression and barbarism and making safe for mankind those moral and spiritual values to which we owe all that is best in our civilization.

It is well that we should remember, however, that although the material burden is largely ours alone, we have the sympathy and often active support not only of those nations such as Czechoslovakia, Poland, Norway, Holland, Belgium whose liberation waits on the success of our arms, or of the great countries across the Atlantic, but also of many Frenchmen still in France. As regards those Frenchmen who have come to Great Britain, the memorandum of agreement recently made between the British Government and General de Gaulle provides for a French force of volunteers including naval, land and air units and scientific and technical personnel, who will fight and work for the Allied cause ; further, such volunteers will be given special facilities for acquiring British nationality.

None the less, if we are to obtain in due course the full results of our efforts, for our allies and well-wishers as for ourselves, we must turn our attention to the history of the last twenty-five years, to probe the real causes of our failure twenty years ago to build a durable world-order, and to be ready to avoid the mistakes of the past when the opportunity to build again is vouchsafed us. As Sir Herbert Parsons points out in a letter in this issue of NATURE (p. 230), it is not too early to take steps to consider the future in the light of experience of the past two decades.

It is this point of view that gives topical interest to Prof. E. H. Carr's "The Twenty Years' Crisis" and to the more recent volumes of Dr. Maxwell Garnett and Mr. Arthur Bryant referred to below*. Prof. Carr attempts to analyse the underlying and significant, rather than the immediate and personal, causes of the present war, and he opens with a discussion of the science of international politics which should make a direct appeal to the man of science. None the less, the scientific worker who reads with keen appreciation Prof. Carr's opening chapter on the beginnings of the science of international politics, with its insistence on the relation between purpose and thought, its reminder that political thought itself is a form of political action, that political science is the science not only of what is, but of what ought to be, its warning about distinguishing the analysis of what is from aspiration about what should be, may yet put the whole book down with some sense of disappointment. Despite all his keen analysis of particular situations, his historian's impartiality and his shrewd comments, Prof. Carr appears to lead us nowhere. His concluding analysis of the prospects of a new international order lacks conviction and definition and offers little that is constructive.

---

* The Twenty Years' Crisis, 1919–1939 : an Introduction to the Study of International Relations. By Prof. Edward Hallett Carr. Pp. xv+313. (London : Macmillan and Co., Ltd., 1939.) 10*s*. 6*d*. net

A Lasting Peace. By Dr. Maxwell Garnett. With some Chapters on the Basis of German Co-operation, by Dr. H. F. Koeppler. Pp. 288. (London : George Allen and Unwin, Ltd., 1940.) 7*s*. 6*d*. net.

Unfinished Victory. By Arthur Bryant. Pp. xxxvi+271. (London: Macmillan and Co., Ltd., 1940.) 8*s*. 6*d*. net.

The reason for this is easily found. Prof. Carr insists that Utopia and reality are the two facets of political science, and the whole book is largely an essay or commentary on the implications of the opposition between Utopia and reality in the light of the history of the past twenty years. Unfortunately, Prof. Carr does not carry his analysis of political objectives or ideals far enough. The distinction between reality and Utopia is never made clear to the reader. The two common meanings of Utopia are confused, and generally the analysis of terms, events or causes is not pushed far enough. Partly as a result of this, Prof. Carr's obvious desire for strict impartiality leads him to do something less than justice to the attempts to build a new world order, whether through the League of Nations, collective security, federation or the like. The opponents of world co-operation are invariably given the benefit of the doubt, despite a reminder that it is by no means certain that a direct appeal to the motive of sacrifice will always fail.

Prof. Carr, in fact, largely overlooks or underestimates psychological factors, and valuable as his work may be as a corrective to wishful thinking, or as a contribution to putting the factors of power and morality in their proper perspective in international politics, or for its analysis of the relations between law and change, it does not make the significant contribution to the science of international relations which might be hoped from its opening part. It should indeed be read with L. Woolf's stimulating essay "Utopia and Reality" in the *Political Quarterly* (April–June 1940)—itself essentially a thoughtful review of the book. None the less there are few recent books which are more worthy of attention from those who are attempting to think out the lines of the new world order.

Prof. Carr regards the fundamental difficulty of reconciling the good of the nation with the good of the world community as due to the breakdown both of the Darwinian doctrine which identifies the good of the whole with the good of the fittest and contemplates without repugnance the elimination of the unfit, and of the doctrine of a natural harmony of interests which, in his opinion, has lost such foundation in reality as it once had and becomes inevitably a cloak for the vested interests of the privileged. Our task of exploring the ruins of our international order and discovering on what fresh foundations we may hope to rebuild it must be considered from the point of view of power and of morality. The form of the future international order is closely bound up with the future of the group unit, and it may well be that the concept of sovereignty will become even more blurred and indistinct. The best hope of progress towards international conciliation seems to lie along the path of economic reconstruction.

L. Woolf dissents from Prof. Carr's view that the doctrine of harmony of interests has lost its validity. He points out that individuals as well as nations often fail to recognize their real interests, and that generally and in the long run common interests are more real politically than conflicting interests. The real international problem which confronts Europe and civilization to-day is not a choice between Utopia and reality but between the psychology of conflicting interests and the organization of power politics on one hand, and the psychology of common interests and the organization of international co-operation on the other. Woolf, however, is himself too legalistic. The transition to a durable peace and a more equitable social order must be in the sequence order, law and good government, as Sir Alfred Zimmern remarks, not law and then order. "No paper plan," insisted Lord Halifax, in a broadcast last autumn, "will endure that does not freely spring from the will of the people who alone can give it life."

Prof. Carr would doubtless concur that education is one of the essential tasks in the establishment of world order. That question is discussed in two of the most important chapters of Dr. Maxwell Garnett's book. The world commonwealth of the future can only be held together by a world loyalty and the invisible bond of ideals, and the problem of building world order on a lasting basis belongs in the long run no less to psychology and education than to politics and economics.

Dr. Garnett deals with the immediate causes of the present conflict and the breakdown of international co-operation. In some respects his analysis of the history of the last twenty-five years is more realistic than Prof. Carr's. In contrast to the latter's cool detachment, Dr. Garnett does not conceal the fact that he is on the side of the angels. He is concerned, however, to lay bare the causes of the failure of the first experiment at international co-operation and world order through the League, and his survey and criticism cannot be dismissed as one-sided or superficial. The ordinary citizen will find his argument much easier to follow, if in some respects less profound, than that of Prof. Carr, and the book is a notable contribution to the educational work which must proceed, both during the War and after it, before we can achieve a lasting peace.

Dr. Garnett quotes the text of the Solemn Declaration of the Supreme War Council of March 28 and obviously visualizes the gradual development of the new international order out of that Anglo-French co-operation. Nor need we fear that the act of one French Government need compel the abandonment of all hope that that co-operation may yet prove the stepping-stone to such a new order when the menace of aggression and barbarism has been removed.

This factor gives special significance to the last part of the book, in which Dr. H. F. Koeppler, under the title "The Basis of German Co-operation", gives a succinct review of German history, particularly the unification of Germany, and discusses its bearing, as well as that of the rise of Nazism, on the establishment of a lasting peace. It is here, as in its stress on the importance of education, that the book touches common ground with Mr. Bryant's "Unfinished Victory", the finest in quality and most moving of the three. Writing with all the impartiality of the historian, Mr. Bryant gives us a study of Germany history from 1916 and an interpretation of Hitler and Nazism which can scarcely fail to facilitate the creation of an understanding between the British people and the Reich when the War has come to an end. The heart of the book is in the introductory "Historian's Testament", with its hope that the book may help in the right use of victory when it has been won for us by the valour and endurance of our race.

Mr. Bryant's sincerity and balance can scarcely fail of their purpose to make it a little easier for the people of Great Britain to understand the causes of the violence and aggression of our enemy, and as he points out, we can only achieve our end of freeing Europe from the effects of that violence and aggression when we have reached that understanding. But few who read the book will fail to be grateful also for the interpretation of the national spirit given in a passage written after the march to Prague. There is in these pages a quality of the spirit which is the surest token that victory won once again will this time not be unfinished or in vain.

These books are permanent evidence that in the midst of this struggle there are those who, recognizing all that it demands of us, are looking to what lies beyond. The reader may well find in their pages, not vain visions or castles in the air, but the quality of mind which will strengthen him to endure all that may be asked of him in the ordeal that lies immediately ahead ; and, when victory is won, to play his part in the travail out of which the new world order will be born. The three books together make no mean contribution to fundamental thinking on the enduring values of Western civilization for which we contend, and on their enthronement in a new order, social as well as international, from which, not change or evolution, but war has been eliminated. Such thought running ahead of realization, as A. N. Whitehead reminds us, is the condition of quick transition to new types of civilization. That it should proceed in the midst of so stern a struggle as that in which we are now engaged may indeed be the earnest of final victory.

ARE WE ALONE IN THE UNIVERSE?

Life on Other Worlds
By Dr. H. Spencer Jones. Pp. xiv+259+17 plates. (London: English Universities Press, Ltd., 1940.) 7*s*. 6*d*. net.

As every professional astronomer knows, there is a vast population of laymen for whom the really exciting problems of astronomy are not those associated with the finiteness or supposed expansion of space, or the sources of stellar energy, but with the canals on Mars and the possibility of life on Mars. In this little book of 250 pages, the Astronomer Royal tells us of the findings of modern astronomy on these latter questions, and much besides, in a way that will not only interest the layman, but the professional scientist as well. It is a model of what such a book should be, popular and scientific at the same time, clear but concise in its writing, with the main theme standing out unburdened by irrelevant details, and the conclusions stated with balance and fairness. If there are any inaccuracies of fact, or even of typography, the present writer has failed to notice them.

Yet the book is something more than a mere exposition of the accepted findings of modern astronomy; here and there the author adduces new arguments, and opens up new vistas of thought. These deserve the compliment of critical examination.

After giving us a thumb-nail "picture of the universe", the author explains why living matter on earth consists largely of compounds of carbon, and why it must probably do so wherever it appears. Life would thus seem to be restricted to a very narrow range of temperature, and this, in conjunction with other quite simple considerations, rules out all planets except the earth and Mars as possible abodes of life. The chapter on Mars, then, must contain the core of the discussion, and its title, "Mars—the Planet of Spent Life", informs us of its conclusions in advance.

We read first of Schiaparelli's discovery of the "canali" on Mars, and of Lowell's attempt to interpret them—in opposition to Schiaparelli's considered opinion—as canals built by intelligent beings to transport water, by a pumping system of 4,000 times the power of Niagara, from polar ice-caps to the equatorial regions. Dr. Spencer Jones rejects this interpretation *in toto*, and indeed he could do nothing else. For the supposed ice-caps are probably not ice at all, but clouds; and even if they were of ice, they could not be more than a few inches thick, otherwise they would not melt away and disappear, as they do, in the chilly Martian summer. Further, while the camera shows that some at least of the "canali" have a true objective existence, it shows them as rows of broken smudges rather than as continuous canal-like structures. Now it is known that the eye, straining to study such a row of dots or smudges in a poor light, will subjectively connect them up into a straight line; Greenwich schoolchildren, when told to copy a badly-lighted map of Mars, not only inserted the features that were on the map. but also systems of "canals" that were not there. Lowell saw many of the supposed canals doubled at distances of about 0·26″, although the resolving power of his telescope was limited to 1·0″. All this makes it clear that the problem must be attacked along other lines.

Mars is commonly supposed to have been formed from the outer layers of the sun, in which free oxygen is abundant, yet the spectroscope shows no trace of free oxygen in the Martian atmosphere. It is reasonable to suppose that the original oxygen has combined with other elements, Mars looks red, and many oxides are red, so that we may conjecture with Dr. Spencer Jones and many others that "Mars may be a planet where the weathering of the rocks, followed by their oxidation, has resulted in the almost complete depletion of oxygen from the atmosphere". But it is surely going too far to say that "the colour of the surface of Mars provides sure evidence of the presence of free oxygen, at any rate in the past", and still more so to continue, "The presence of free oxygen almost certainly demands the existence of vegetation". Surely the observations are most simply explained by supposing that the free oxygen which came from the sun has all, or nearly all, been absorbed by the rocks; the question of vegetation does not come in at all, except that if there were abundant vegetation, we should expect to find abundant free oxygen in the atmosphere, which we emphatically do not.

The author finds a further argument for the existence of vegetation in the seasonal colour-changes which occur on the surface of Mars, certain areas turning dark green, or at any rate dark, in the summer. Here he is again in company with many other astronomers. He rejects Arrhenius's suggestion that the areas in question may be covered with soluble or hygroscopic salts which change colour in rainy weather. He might have added that Lyot's recent careful studies of the reflecting and polarizing qualities of the surface of Mars seem to indicate that this consists of volcanic ash—like the moon.

Beyond the solar system the question of the existence of life becomes a matter for speculation controlled only vaguely by theory. If we are right in believing that planetary systems can only come into existence through the close meeting of two stars, then only a minute proportion of the stars can be accompanied by planets. Even so, there are so many stars in space that the total of planets must be large, and many of these must be in a condition to support life—if it comes. But will it come? Dr. Spencer Jones gives us little help here, telling us, on the first page of his preface, that he assumes life will come whenever the conditions are favourable; others may prefer to make the opposite assumption. Here is the question which, because of its philosophical and religious implications, interests the layman most, and the astronomer as such can give him but little guidance. We know of two, or at most three, planets on which the conditions are suitable for life. The earth falls out of any statistical discussion, because we should not be discussing the problem if life had not come to it. Venus is almost certainly too hot—and Mars? Clearly there is not yet adequate material for statistical discussion.

J. H. JEANS.

FRUITS OF THE RENAISSANCE IN ARCHÆOLOGY

The Prehistoric Foundations of Europe to the Mycenean Age
By C. F. C. Hawkes. Pp. xiv + 414 + 12 plates. (London: Methuen and Co., Ltd., 1940.) 21s. net.

THE past twenty years have seen an astonishing development in a broad field of historical study of which natural scientists have often been more aware than the majority of historians. Even the bare outlines of human history in Europe for more than nine-tenths of the total period of human occupation could not be indicated in 1920. The fruits of intensive work in prehistoric archæology at a multitude of sites revealing cultures separated in time by hundreds of thousands of years may to-day be co-ordinated securely enough, not merely to establish the outstanding phases of the culture history of Europe down to Classical times, but also to point with confidence to many of the physical and sociological conditions involved in the series of technical revolutions, migrations and territorial consolidations which occurred. The natural scientists have become acquainted with these remarkable achievements because their co-operation has been successfully sought in attacking a multitude of technical problems on which the delineation of this complex field of culture history has depended. To the anatomists and physical anthropologists have been referred problems of racial evidence for connexion and migration; the palæobotanists and geologists have provided techniques for the construction of prehistoric time scales, and have in their turn been aided by the archæologists, who have provided type fossils for their own problems of zoning. Mineralogists and chemists have made vital contributions to problems concerning the conditions and scenes of the decisive metallurgical and other technical advances of prehistoric times.

Mr. Hawkes's masterly survey of the greater part of this vast prehistoric field, the cultural development in Europe from the time of the first palæolithic occupants to the establishment of the 'cultural balance' of the Middle Bronze Age in the second millennium B.C., is from this point of view a repayment for these many contributions from the natural sciences, contributions the significance and importance of which are made clear in the course of his complex narrative.

The renaissance of European prehistory in Great Britain may be said to date from the publication of Crawford's "Man and His Past" (1921) and the first edition of Childe's "Dawn of European Civilisation" (1925). Before this prehistoric archæology was still very largely the grubby handmaiden of the conventional historian, the folklorist and the evolutionary technologist. Archæological data were too often conceived as useful merely for buttressing or refuting historical hypotheses based on literary records, legends or *a priori* theories of social and technological development. Flintwork and pottery, celts and swords were usually regarded only as the alleged, and often inadequately alleged, products of dimly conceived 'races' or stages of human development. The revolution in outlook consisted essentially in attempting to build up by every means possible without reference to preconceived theories of origin, as full a picture as possible of the culture, time point and physical environment of the society whose members had used the artefacts discovered by chance or excavation. The amazing measure of success which has been achieved and the multitude of painstaking investigations which have contributed to the pictures Mr. Hawkes is able to present will be immediately clear to the reader of his book.

Archæology once obsessed by relics of lost 'races', by intimations of the 'pagan rites' of our 'ancestors', is now moving towards a position in which the historical geography, the sociology, economies and the religious systems of the human race may be adequately sketched from the ultimate dawn of history, the emergence of man. In the first phase of this advance there was a marked emphasis on environmental control of prehistoric cultures; later, under the stimulus of Prof. Childe's brilliant analyses, the economic revolutions of prehistoric times and their technological bases have formed the framework for classification and narrative. One of Mr. Hawkes's major contributions is to bring back into focus the sociological implications of culture contacts and in particular the rise and expansion of dominant groups and of their ritual systems. Some earlier studies have too often left one with an impression of prehistoric groups as pawns of the European forests and loess; the emphasis on economic forces, while never deterministic, has also on occasion obscured the fact that a society is never merely an economic organization, that social values other than immediate economic advantage may be spurs to cultural change and, in particular, that there are indications of the effects of mystic zeal and the potency of religious symbolism in the culture spreads of prehistoric Europe. In his treatment of both the

Ægean cultures, of the role of the 'megalithic religion' in Atlantic lands and of the cultural unification imposed by the Warrior peoples of Central Europe, to cite but a few examples, Mr. Hawkes has restored the balance. He formulates hypotheses of social organization for every adequately documented culture and, while some may have to be revised in the future, the foundations of the social history of prehistoric Europe have been soundly laid.

In its plan and general organization this study follows broad lines which will be familiar to students of European prehistory. It is remarkable not only for the balanced and catholic treatment of the main trends, but also for the wealth of detail which Mr. Hawkes, revealing extraordinary command of the vast and scattered literature, has contrived to incorporate in his narrative. Making use of every stylistic device for compression he has been able to illustrate and discuss in some detail every cultural phase and problem. Nor is this only a compendium of current views; quite often, as, for example, on the source of the Danish 'dolmens', on the introduction of cremation rites in northern Ireland and in disentangling the complexities of the ceramic tradition in Early Bronze Age Central Europe, new approaches and hypotheses are offered. It must be admitted that the compressed and parenthetic style make considerable demands on the reader's attention; but his patience is rewarded by a full and critical treatment in extraordinarily small compass. The plates and assemblages of line drawings have been selected with great skill, and admirably document the text; but the maps are less successful.

DARYLL FORDE.

GEOLOGICAL HISTORY AND MINERAL RESOURCES OF SOUTH AFRICA

The Geology of South Africa

By Dr. Alex. L. du Toit. Second edition, revised and enlarged. Pp. xii+527+41 plates. (Edinburgh and London: Oliver and Boyd, 1939.) 28*s*. net.

SOUTH AFRICA, paradise of geologists, continues to bring forth its treasures. For many generations it has supplied the world with gold, diamonds, platinum and corundum, while in recent years the development of its resources in other essential minerals, such as tin and tungsten, has become increasingly important. In the realm of palæontology, it has furnished, from the rocks of the Karroo System, a wealth of well-preserved material for evolutionary studies in early reptiles, amphibians and fishes. Archæologists, too, have looked upon this region as a happy hunting ground, for within the last few decades it has yielded skeletal remains of early man and anthropoid apes, as well as a large series of primitive stone implements.

From the moment the visitor to South Africa sights Table Mountain his eye is arrested and his imagination fired by the peculiar and distinctive scenic types of the country; he is held in wonder by the kopje landscapes, the great cliff of the Drakensberg, the desert wastes of the Kalahari, the granite weathering of the Matoppos, and the mysterious Great Dyke of Rhodesia. The geological pilgrim especially is impressed by the knowledge that, on not less than five (and possibly even more) occasions the country has undergone the vicissitudes of Ice Ages, all of great antiquity, occurring in pre-Cambrian, Cambrian (?), Devonian, and Carboniferous times. In some of these periods the area may have been near the periphery of the great ice-sheets, so that it received only scratched pebbles and erratics dropped from melting icebergs or ice-sheets, but in late Carboniferous times, when the world-famous Dwyka deposits were formed, there was evidently a widespread glaciation that radiated westwards and southwards from the region that is now the Transvaal. The Dwyka deposits show beautifully preserved examples of glacial floors, pavements, roches moutonnées, disturbance, striæ, chatter-marks, varve-like clays and the like. So remarkable, indeed, are these phenomena, that the Union Government has wisely decreed that the Nooitgedacht Farm area, where they are exceptionally well exposed, shall be established as a natural reserve, just as the Glacier Garden of Lucerne is preserved as a testimony of the much more recent Pleistocene glaciation. (Curiously, Nooitgedacht has escaped mention in the index.)

These and many other equally interesting subjects are discussed in Dr. du Toit's book, now the standard work on the "Geology of South Africa". The volume appeared in its first edition in 1926 (reviewed in NATURE of May 7, 1927). In the second edition, the work has been revised throughout and, in consequence, somewhat enlarged. The accompanying coloured geological map has been corrected and brought up to date; it includes

Southern but not Northern Rhodesia. Among the chapters that have been expanded are notably those dealing with the Witwatersrand gold-mining area, the economic resources of South Africa, the Ventersdorp volcanic series and the petrology and tectonics of the Vredefort Dome.

The results of recent geological investigations have been incorporated, as, for example, in the revised classification and subdivision of the "Primitive" or oldest Pre-Cambrian rocks, and in the account of the characters and distribution of the Nama System, a rock-group assigned to the Cambrian or latest pre-Cambrian on the evidence of its fossils, which appear to have affinities with the Archæocyathidæ, sponges and stromatoporoids. Similarly, in his account of the Vredefort "Dome" of granite, an extraordinary mushroom-shaped structure "of truly amazing character", the author has summarized the later work of Molengraaff and Hall, and of S. J. Shand.

The problem of the mode of origin of the gold emplacements in the Rand conglomerates (or bankets) is discussed at length, and, notwithstanding the recent attacks of Graton and others on the placer theory, Dr. du Toit expresses the opinion that the majority of geologists acquainted with the deposits adhere to the view that the gold is largely detrital in origin, while not denying that local enrichment has been caused by infiltration. In his extended account of the geology of the Rand the recent development of the Far East Rand and the West Rand is considered in relation to the parent area.

From his own observations in South America, the author is able to institute valuable comparisons between the Devono-Carboniferous stratigraphical succession, facies and structures on the two sides of the Atlantic, and to direct attention to the support that in his opinion these similarities give to the Wegener hypothesis of the drifting apart of the two continental masses.

Although the Great Ice Age as we know it in the northern hemisphere left no evidence of glacial and interglacial epochs in South Africa, a succession of early human industries resembling that in Europe has now been established. Much has still to be done before the stages of cultural development and the climatic oscillations (such as the three wet phases and an arid phase in the Vaal River Basin) can be regarded as satisfactorily correlated, but the valuable contributions to this end by C. van Riet Lowe and his colleagues are usefully summarized.

High praise was extended on the appearance of the first edition of this book. The second edition is even more praiseworthy. The volume is a masterly compilation, attractively written and well illustrated ; it will long be used with appreciation by all interested in South African geology.

P. G. H. BOSWELL.

SURVIVALS AND BELIEFS

English Folklore

By Christina Hole. Pp. viii+184+33 plates. (London : B. T. Batsford, Ltd., 1940.) 10*s*. 6*d*. net.

IN her introduction to this collection of English popular beliefs and customs, the author remarks on the relative poverty of the English tradition in this respect when compared with that of the Celtic-speaking peoples of Scotland, Wales and Ireland. This is in accord with the principle that such peripheral regions as a rule are found through their conditions to have afforded a favourable environment for the survival of the more primitive elements in a culture composed of diverse elements. The resistance of the Celtic-speaking elements in the British population to conquest has also fostered the preservation of tradition.

As a consequence, students of popular custom in Britain have shown a not unnatural tendency to direct their investigations to the richer material of the outlying regions, where the continuity of tradition, though not entirely free from outside influence, on the whole has suffered less dislocation than in England, which has not only been overrun by a succession of invasions by Saxons, Danes and Normans, but also in more recent times has been more completely subjected to the levelling influence of the contacts with outside peoples which has proceeded *pari passu* with the development of communications. Yet, as has frequently been pointed out, this makes of English folk-lore an interesting and at times informative field of cultural analysis.

Miss Hole has drawn her material in part from personal inquiry, in part from printed sources. Of these the more important and fruitful, almost inevitably, have been the invaluable volumes of county folk-lore published by the Folk-lore Society. The classification which she has adopted under the headings of "The World of Everyday", "The World of Nature" and "The World of Magic", has enabled her to cover systematically a field which from the very nature of its content invites inevitably to scrappy treatment. In the first group of beliefs she deals with those which surround the individual from birth to the grave; the second illustrates the attitude of the individual to sun, moon and stars, birds and beasts, trees and plants, and water, wells and stones; and in the third division we have his relation with aspects of the unseen, the world of spirits, manifested in beliefs relating to witches and fairies.

While it is true that much of folk-lore custom died out before the nineteenth century came to an end, this applies more particularly to communal practices enshrining old and forgotten beliefs rather than those more personal survivals from which Miss Hole has drawn a rich selection. Of the more elaborate ceremonial customs, such as, for example, the Abbots Bromley horn dance, probably few would now survive had it not been for the efforts of Cecil Sharp and his colleagues and successors to preserve and revive folk-dance, song and drama. Yet notwithstanding the advance of education, beliefs affecting the individual survive in abundance. The reason is here made clear. It is fear, fear of ill-luck and the unknown. It is therefore not surprising that among the most recent examples quoted are measures to avert the evil influence of the witch. It is, however, interesting to find that Herne the Hunter, his blasted oak, and the white stag, portents of calamity, all appeared in Windsor Royal Forest before the economic crisis of 1931.

ULTRA-VIOLET LIGHT IN TECHNOLOGY

Fluorescence Analysis in Ultra-Violet Light
By J. A. Radley and Dr. Julius Grant. (Monographs on Applied Chemistry, Vol. 7.) Third edition. Pp. xvi + 424 + 34 plates. (London: Chapman and Hall, Ltd., 1939.) 22*s*. 6*d*. net.

THIS valuable work deserves the third edition which it has now attained in a little more than six years. It is twenty per cent larger than its predecessor in the text, in the number of references, and in five more large plates. These last include a photograph in ordinary light and a photograph in ultra-violet light of the faded writing in the Peniarth manuscript, which illustrate in striking degree the possible usefulness of the fluorescence method of examining such museum documents. An even more interesting instance, not illustrated by a plate, is the discovery of alterations in the concluding verse of St. John's Gospel in the "Codex Sinaiticus".

The final chapter (xx) on "The Dyestuffs Industries" is a very useful addition to the book. The general information is very meagre, but there is a wealth of data showing how fluorescence phenomena are influenced by solvents, temperature, inhibitors, decay, etc. on various colour agents. Unfortunately, a few of the paragraphs are borrowed from Chapters xiv on "Organic Chemistry" and xviii on "Textiles" in the last edition, where this part of the subject was then inadequately treated.

Chlorophyll, which came under the general heading "Identification of Colouring Matters" in the second edition, is bereft of any such association, having lost the companionship of "vegetable dyes", which now receive notice in the last chapter. Indeed, the "Identification of Colouring Matters" as a separate section ceases to exist; and the expression does not occur on p. 387, to which the index directs the reader.

Chapter iii deals at considerable length with the subject of "Filters", especially with glasses, and gives many details relative to the composition of glasses. Nevertheless, it appears to make no mention of the well-known didymium glasses, even though it pays tribute to the researches of Crookes in this field (p. 25). It is not clear why "Wood's glass" and the like (p. 33) should be included under "Filters other than Glass", away from "Glasses which Transmit Ultra-Violet Light" (p. 27). This has persisted from the first edition. Perhaps the most remarkable omission in these days of A.R.P. is that there is no mention of luminous paints, or of various fluorescent phenomena which have so long been utilized for advertising and similar purposes. A discussion on the technology of these subjects would be quite out of place in a work devoted to "Fluorescence Analysis", but surely there are analytical aspects which claim suitable notice.

As in the previous edition there are numerous inconsistencies in the text, some merely a matter of English, others technical. For example, on p. 27 one would welcome some comment or explanation by the authors on taking ordinary window glass as unity, even if on the authority of some other worker. Similarly, on p. 1, what was the quality of the glass plate 7 mm. thick which transmitted certain percentages of light at various wave-lengths?

However, the new edition marks a distinct advance on its predecessor, and bids fair to enhance its established reputation. S. J. L.

EFFECT OF NOISES OF WARFARE ON THE EAR

By Dr. T. S. Littler,
University of Manchester

THE rapid development of high-explosive weapons of destruction and attack accompanied by increased blast effects has necessitated increased protection against the possibility of physical injury. The dangers of destructive effects on the sense organs though less obvious have become increasingly serious, and of these impairment of the sense of hearing is of considerable importance. The disturbances likely to endanger the aural and nervous system during bombardments or air raids consist mainly of intense sudden noises of an explosive character. Much information is available on the effect on the ear of these intense noises, and to a certain extent it is possible to minimize or mitigate possible damage to the aural system. Less intense sounds of longer duration which are sometimes referred to as 'horrific noises' and which the enemy have recently introduced as a form of aerial warfare can of themselves produce no damage to the ear. Their panic effect is a psychological one and is calculated to be enhanced by surprise when used without regularity.

The human ear has an upper limit of acoustic pressure beyond which the sensation of sound is accompanied by a sensation of feeling or pain. This limit, known as the threshold of feeling, is a practical upper limit not only for sounds which can be sensed by the ear but near which prolonged exposure may cause damage and temporary or permanent loss of hearing acuity. The acoustic pressure required to attain this limit depends on the frequency of the sound. It is about 3,000 dynes per square centimetre for frequencies of the order of 30–100 cycles per second, but it is only about 600 dynes per square centimetre over the range 200–7,000 cycles per second[1]. Much work has been done on the effect on the ear of intense sounds at pressures approaching the threshold of feeling, and it has been found that such sounds produce definite aural fatiguing effects—effects which may remain for some hours if the sound is sufficiently intense and maintained for a sufficiently long period but from which the ear ultimately recovers. Subjects who have been in the presence of intense noise for very long periods are known to become permanently deaf to certain ranges of frequencies. In the majority of instances the deafness occurs for the upper audible frequencies and corresponds to an inner ear defect near the basal turn of the cochlea.

From experimental evidence it seems that in the case of complex sounds with different wave forms the peak excitation of the basilar membrane is nearer the basal turn of the cochlea the steeper the wave form[2]. It is to be expected, therefore, that greater peak pressures can be endured for slowly rising wave forms than for steeper wave forms. Although the blast pressure encountered during a high-explosive bomb explosion is probably of the order of 10^8 dynes per sq. cm. (100 atmospheres) at the point of explosion, the pressure dies rapidly to the order of 10^6 dynes per sq. cm. (1 atmosphere) a short distance away, after which the disturbance becomes a progressive wave of pulse form in which the pressure decreases linearly with distance from the source. The time interval during which the pressure rises from the undisturbed state to that of maximum condensation depends on the nature of the explosion, but in the case of the high-explosive bomb it is of the order of two or three milliseconds. It is apparently this sudden rise of pressure that produces the greatest

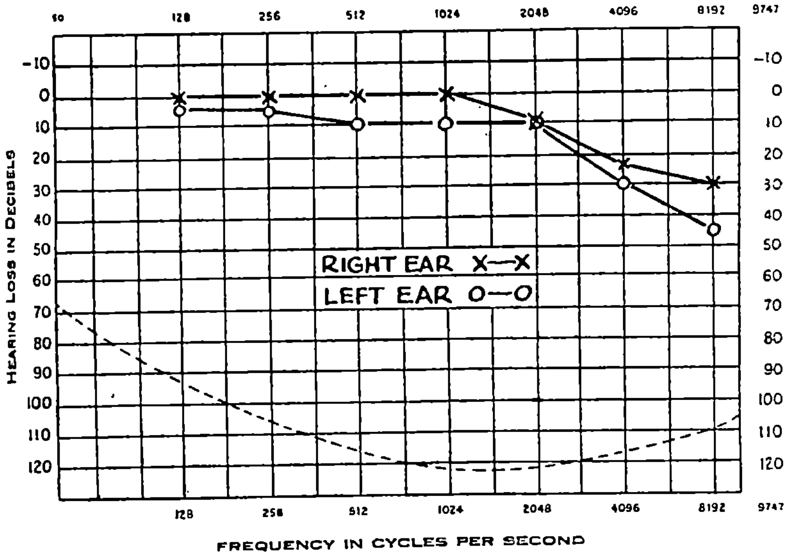

Fig. 1.

AUDIOGRAM OF PILOT SHOWING PERMANENT HIGH-FREQUENCY DEAFNESS PRODUCED WHEN THE EARS ARE UNPROTECTED.

damage to the aural system. This is observed in the case of exposure to gunfire, where it is found the smaller the gun the sharper and more distressing the sound.

Valuable information on the effect on the ear of intense sounds of steep wave front is obtained from hearing tests of aviators before and after certain periods of flying in aeroplanes where the peak acoustic pressure may reach or even exceed that corresponding to the threshold of feeling for pure tones[3]. It has been found that, after flights of one hour in modern types of aircraft, pilots show a severe hearing loss to frequencies in the upper register above 2,000 cycles if the ears are not protected in any way. This deafness is temporary and the subject recovers to normal after a certain period of rest, but if flying is continued for long periods without protection to the ears the deafness becomes permanent. The pilot is not always aware of the disability owing to the high frequencies involved affecting the clarity rather than the apparent loudness of speech received, but an audiometer test demonstrates the defect quite clearly. These results are illustrated in the audiograms of Fig. 1 showing the hearing loss produced in the case of a pilot after a flight of one hour. This temporary deafness does not occur if a helmet or a satisfactory earplug is worn. Fig. 2 shows the hearing curve representative of the type of permanent hearing loss produced after about 200 hours flying without any form of protection for the ears. Now hearing tests made on pilots who have always worn a flying helmet or protected their ears in some way show that hearing can be retained at normal level even after very long periods. For example, Fig. 3 shows the hearing curve of a pilot, representative of many others, who has had a total flying experience of several thousand hours, but has always worn a helmet or protected his ears. The acoustic insulating properties of a flying helmet and of a number of earplugs are given in the accompanying table, where it can be seen that although great insulation is produced for high frequencies the reduction of incident sound for frequencies below 500 cycles per second is very small. Since the main components in aeroplane noise are in the lower frequencies such plugs do not seriously reduce the peak pressure in the wave falling on the eardrum, but by virtue of their high insulating properties at high frequencies they reduce the steepness of the wave front appreciably, thus producing a less damaging sound on the ear.

In the case of explosive sounds the deafening effects are due to single blasts and are of the same nature as aviator's deafness. A detailed study of these has been made by Bunch[4]. In general, there

AUDIOGRAM OF PILOT WHO HAS ALWAYS PROTECTED HIS EARS.

TESTS OF METHODS OF EAR PROTECTION

Methods

1. Flying helmet firmly strapped so that the telephones and their holders closely seal the ears.
2. Ear defenders.
3. Finger tips in ear.
4. Cotton-wool saturated with 'Vaseline'.
5. Liquid paraffin and cotton-wool saturated with 'Vaseline'.
6. Liquid paraffin and cotton gauze saturated with 'Vaseline'.
7. Meatus packed with 'Plasticine'.

Protection stated as hearing loss in decibels.
(Measurements by air-conduction from a loud-speaker source.)

	Method	1	2*	3	4	5	6	7
Frequency of test	250	5	15	20	15	15	10	10
	500	—	10–30	—	15	20	15	10
	800	15	15–25	25	15	25	25	10
	2,000	25	15–40	25	15	25	40	20
	3,000	—	10–45	—	30	35	40	25
	4,000	35	25-55	35	30	50	50	35

* It proved impossible to fit defenders into the ears with equal tightness in successive tests because the material of which they were made was hard and failed to adjust itself to variations in the shape of the individual meatus.

seems to be no doubt that the parts of the cochlea near the basal turn corresponding to high frequencies are more exposed to shock excitation and the first to suffer any degenerative effects. Stevens and Davis[5] are of the opinion that violent stimulation causes disruptive effects which involve temporary or permanent damage to the hair cells. There are instances where explosive sounds actually produce a rupture of the tympanic membrane, but of itself this is not of a serious nature as the membrane heals rather rapidly—it is the inner ear with its sensitory contents that is so easily damaged. In addition to the effects referred to above, Yearsley[6] points out that true concussion of the labyrinth may occur as a result of a high-explosive wave and reports instances of deafness allied to hysteria after burial in earth thrown up by an explosive.

The methods of protection of the ears against explosive sounds are very simple. One of these, the earplug, has probably been in use for more than a century and has always been used extensively by gunners and others in the presence of intense noise. The other is the buffer, which is a wedge of rubber or resilient material held between the teeth. It is believed to prevent the full shock of an explosion from being conveyed through the bones of the skull. Relaxation of the face muscles, in reducing the rigidity of any exposed part, is an additional protection which reduces blast effects. The table gives some idea of the efficiency of simple plugs. A supply of these such as cotton-wool soaked in 'Vaseline' can easily be carried about the person as a precaution, and in the case of children pads strapped on the ears are an alternative. Earplugs made of hard material are not advisable as they are apt to produce irritation after long periods of use and they have little advantage over more resilient obstructions.

THE CELLULOSE PROBLEM IN WAR-TIME

By Dr. Julius Grant

FROM time to time I have discussed in NATURE[1] and elsewhere[2] some of the problems which face those in the paper, rayon and other industries which rely on fibrous cellulose as a basic raw material. Since some of the most important of these problems have always been subject to the balance of supply and demand, it is not surprising that under war-time conditions they should have acquired a new aspect. In the ten years prior to the War the production of cellulose pulp, particularly from wood, fluctuated uncertainly between a state of inflated prices to one of unprofitable over-production; immediately before the War, in fact, there were even 'scares' of a cellulose pulp shortage. These, however, were scares in the true sense; they did not bear a scientific survey of the cellulose resources of the world, particularly when alternatives to wood pulp were taken into account (see Grant[3]).

It is indeed an interesting reflection on the nature of a situation which aroused so much discussion at the time, that it should so soon have been forgotten. However, the war-time situation which confronts the cellulose-using industries may be summarized briefly as follows; incidentally, it is one of special interest to scientific workers, who rely on the printed word as an essential medium for the spread of information. The extension of the War to Scandinavia has cut off from Great Britain most of her supplies of wood pulp, which were drawn, in order of importance, from Finland, Sweden and Norway. Events in the Mediterranean may well render increasingly difficult the shipping of esparto grass from French African ports, thereby accounting for almost another fifth of our requirements. The only other direction to which are we able to turn is towards Canada, and increasing quantities from that source will no doubt provide us with most of our really essential requirements ; the potential output of Canada certainly is equal to this.

On the other hand, Great Britain is not alone affected. The United States, for example, is by no means self-sufficient in wood pulp supplies, and they have had to rely in the past on Scandinavia for about 1,500,000 tons and on Canada for some 500,000 tons of wood pulp per annum ; with the loss of the former source they too are turning to Canada, and of course for several obvious reasons the latter is better placed to export to them than to us. The threatened wood pulp shortage, therefore, has at last materialized, although in a very acute and unexpected way, so that it is appropriate to review the situation once again in the light of these new events, and to assess the part which the scientific worker can play in dealing with it.

In the first place, the shortage is probably at its most acute stage now. Its severity has caught most consumers unawares, but assuming a long War, as time goes on the output of wood pulp in both Canada and the United States will increase, and the situation consequently will be eased. It may, nevertheless, be assumed with safety that if the War lasts, and if events take even the most favourable turn from the point of view of the supply of wood pulp to Great Britain, a serious shortage will still persist. It seems, therefore, that we must give some consideration to the production of cellulose pulp from such raw materials as are available in Great Britain.

At present these may be regarded as of three classes, namely, materials in use prior to the War, waste paper and new materials. The first category is comprised almost wholly of what are usually called 'rags', although they include materials as far apart as cotton linters and sacking. It is obvious that even under the most zealously organized system of salvage there is little likelihood of an increase of any real importance in the amounts of these available.

Much, too, has been heard on the subject of waste paper ; but here again, although a great deal has been done and much still remains to be done in the direction of salvage, it is evident that a system which brings no new grist to the mill cannot be a complete solution to the problem. Moreover, every time that the cellulose fibre undergoes processing for paper-making it is degraded in quality ; its length—an important factor in determining the response of the fibre to the processes of fibrillation which occur during beating—is decreased, and it loses its capacity for felting, with consequent detriment to the strength and character of the paper. Eventually, in fact, it behaves very much as an 'organic loading', contributing only weight and closeness of texture. A certain amount of virgin fibre must therefore be introduced into many papers in order to provide a 'skeleton', and the more often that a paper is re-used, the greater the proportion it requires ; or conversely, the poorer the grade of paper into which it can be incorporated. In addition, it must be borne in mind that as a result of the recent drastic restrictions in the use of paper the quantities coming back as waste will be correspondingly reduced.

In this connexion there is one aspect of the recovery of waste paper which deserves special attention, and this is the degree of degradation which takes place as the result of the fibre-recovery process itself, as distinct from the process of actual re-manufacture of the recovered fibre into paper. Recovery processes are numerous ; but they usually comprise two stages, namely, disintegration and purification. The former is mainly mechanical in nature, that is to say, the whole or shredded sheets of paper are agitated violently, usually with hot water which often contains free alkali, the purpose of which is to dissolve the resinous size which coats the fibres and helps to bind them together. It seems that this part of the process allows of little modification which might decrease the extent of the degradation of the fibre. The other stage of the process is, however, mainly chemical in nature, and varies according to the impurities present. The most important of these is usually ink, and the problem may differ considerably according to the nature of the ink. Thus, writing ink is removed with comparative ease with the aid of bleaching agents, and bleaching powder figures prominently among those used in spite of its adverse effect on the strength of the fibres.

Unfortunately, writing ink seldom occurs alone ; it is almost always accompanied by printing ink, and since most common printing inks are made up on a carbon basis, the question of removal becomes more difficult. The scientific basis of printing ink removal depends, first, on the destruction of the medium (usually an oil) in which the ink is compounded ; secondly, on the removal of the particles of the carbon from the fibre ; and thirdly, on the separation (after their removal from the fibres) of as many of these particles as possible, with a minimum loss of the fibres. The first requirement is easily satisfied by the use of alkali, so long as the oil is saponifiable, and it is assisted materially by the use of emulsifying and wetting-out agents. Newsprint inks, however, are made up with mineral oils, and are therefore an exception. Fortunately such oils have a relatively poor binding effect on the carbon, and this to some extent compensates for any difficulty in decomposing them. Owing to the chemical inertness of the carbon, however, its removal from the fibres depends almost entirely on mechanical action. The mechanism underlying removal in this way is still imperfectly understood, and is proving a fruitful field of investigation; it seems, however, that under suitable conditions of combined rapid flow and agitation the individual fibres may be made to scour one another mechanically, and so to remove the particles of carbon on their surfaces. As might be expected, the presence at this stage of substances having detergent or wetting-out properties is again advantageous, and these are frequently used. This stage of the operation, therefore, need have little influence on the quality of the fibre.

The final stage, namely, separation of the particles of carbon, is the most difficult of all, because both the fibres and the carbon have dimensions and specific gravities of the same order, thereby eliminating to a great extent selective flotation or screening methods. In general, the greater the degree of cleanliness required the greater is the loss of yield at this stage owing to removal of fibre with the carbon. However, some degree of success has been achieved by the use of substances producing a froth which collects the carbon and so enables it to be skimmed off; froth-formation, unless it can be controlled, is, however, definitely objectionable. It is sounder to add an adsorbing agent such as china clay, or bentonite, or to precipitate an amphoteric oxide (for example, silica) *in situ*, as these fix the carbon by adsorption and later can be separated with it by means of a washing-drum. Where a final high quality is not of the first importance a compromise may be struck by separating most of the carbon (even at the expense of loss of yield), and dispersing the remainder in a very finely divided state throughout the bulk of the fibres. If this is done efficiently the particles of carbon cannot be seen as such; the final pulp is merely a shade more grey.

Devices of this nature have in common the reduction of damage to the fibres to a minimum. Nevertheless it is apparent that even under the most favourable technical and economic conditions, the re-use of waste is not a complete solution to the cellulose problem. There remains, therefore, the third alternative, namely, the utilization of home-produced raw materials. Numerous factors determine whether a particular material can be used in peace-time as a source of cellulose. In war-time some of these (and especially those which refer to cost) are of less importance, but the essential criteria remain. In order of importance these are: (1) availability (that is, regularity of supplies, quantities available, and ease of harvesting, collection, etc.); (2) yield; (3) ease with which the non-fibrous constituents may be removed (or quality of the final pulp); (4) suitability of existing plant for dealing with such raw materials; and (5) cost. In peace-time the order is different; cost and quality come nearer the head of the list, whilst the necessity to use existing plant is of less importance.

It should be pointed out at this stage that practically every vegetable material of a fibrous nature may be converted into cellulose pulp of one kind or another, and that ever since the shortage of rags which arose after the invention of paper-making by machine in the early nineteenth century, projects have been put forward for the utilization (for paper-making, at least) of every conceivable vegetable material from manure, peat and nettles to tree-wood. It is therefore highly significant that in spite of all this the cellulose requirements of Great Britain should have been derived solely from three raw materials of vegetable origin, namely, wood, esparto grass and 'rags'; indeed, the two latter account for only about 20 per cent of the total and are used only by virtue of special properties they possess. The position is much the same elsewhere in the world. Esparto is not used to any great extent, but in its place may be set various fibrous materials which, owing to local conditions, are favourably placed; straw in Holland, and bamboo in India are examples.

The reason for this is apparent if one applies the criteria of suitability set out above, because in almost every instance the question of cost proves to be the deciding factor. It has, in fact, ruled out everything except waste products (that is, materials for which there is no other use), and even then costs of collection and transport, combined possibly with poor yields, have brought the price of the final pulp to a figure which is not competitive with that of wood pulp. Since this is the case, under war-time shortage conditions one of the principal objections is removed, and the whole question may be reconsidered in this light. The result is that many home-produced raw materials which were previously rejected on the basis of the above criteria, now become interesting possibilities.

By far the most important of these is straw. It is a crop which is produced regularly and in large quantities; it can be collected and handled relatively easily, and its yield of bleached cellulose pulp (35–40 per cent), though on the low side compared with, say, esparto, may be regarded as satisfactory. There are, it is true, other uses for straw in the farming industry, but under modern conditions it is no longer essential for many of these, and it seems that the quantities available are adequate to safeguard a large proportion of our war-time cellulose requirements. Fortunately, too, straw may be processed in most of the existing plant previously used for rag and esparto; certain modifications are required, but these are of a minor character, although owing to the bulky nature of the original straw and the difficulty of packing it into the digesters it is not possible to obtain the same output.

In Great Britain the only pulp plants available for such purposes are those operating an alkali process. The straw is then boiled in digesters under a pressure of 50–60 lb. per square inch with 15–20 per cent of its weight of caustic soda for some three hours. Under these conditions those constituents of the plant structure (such as lignins, pectins, gums, resins and carbohydrates) which serve to cement the cellulose fibres together, are rendered soluble, leaving free the skeleton of cellulose fibres. The cellulose is, however, not entirely unchanged, but undergoes a process the chemical nature of which is as yet imperfectly understood, although it appears to be allied to mercerization. The result is that the pulp acquires a greasy or gelatinous consistency which renders difficult the subsequent operation of removal of the soluble impurities by washing. Furthermore, the manufacture of paper from cellulose pulp is essentially a drainage process, and this, too, is retarded if the pulp is at all gelatinous. This is a characteristic of straw which makes it much more difficult to deal with than, say, esparto, and it presents a problem which may be attacked in two ways, namely, by improvements in methods of washing or by carrying out the digestion under less drastic conditions.

If the latter course is adopted the decomposition of the non-cellulose impurities may be less complete, and this applies particularly to those in the parts of the straw (such as the nodes) where the physical structure is more dense; it applies also to extraneous fibrous matter such as weeds. Certain of these (such as the dock) are far more resistant to attack by alkali than is straw itself, and when even a few of these partly digested particles are broken up in the subsequent operations, they appear in the final product as numerous small brown specks, known collectively as 'shive'.

In spite of this, however, the gelatinous character of straw pulp is such a serious drawback that further work on the elimination of shive becomes most desirable. One method of attack has been by means of a modified method of bleaching[2]. In the past the operations of digestion and washing have been followed by the addition of an excess of a solution of bleaching powder, the residual bleaching agent being washed out when the pulp has attained its maximum colour. One advance on this has been the bleaching of the pulp in two stages, about one half of the total quantity of bleaching agent required being first used; when this is exhausted the pulp is washed, and the remainder of the bleaching agent is added. The principal advantage of this method is the economy in bleaching agent which it effects; but it has also led the way towards further improvements (also along the lines of bleaching in stages) which have enabled more resistant materials such as weeds to be dealt with.

The most important of these is based on a principle similar to that of the original Cross and Bevan method of isolating cellulose, namely by chlorination. The first stage of the process, therefore, is treatment with chlorine, either as gas, as chlorine water or as an emulsion of the gas in water. If it is carried out under the correct conditions this stage has the effect of chlorinating the lignin almost selectively, with the formation of hydrochloric acid from the hydrogen atoms so displaced. If the pulp is then made alkaline, this acid is neutralized, and the chlorolignins are dissolved, so that after it has been washed the pulp is ready for the real bleaching operation, which is carried out with bleaching powder solution in one or more stages. Processes of this kind make possible the treatment of the more resistant plant materials, especially if these contain much lignin, and moreover the degradation in strength which inevitably accompanies the purification action of chemical reagents on cellulose is minimized. If, however, such processes are to be used to the best effect they require careful control; the influence of working conditions such as the concentrations of pulp and of bleaching agent, temperature, *p*H value and time are all of importance, and are the subject of active investigation.

So far special reference has been made to straw, partly because from the point of view of supplies it is the most promising source of cellulose available in Great Britain, and partly because elsewhere (and notably in Holland, Italy, and South America) it has already played an important part in supplementing or displacing wood pulp. There are, however, a number of likely though possibly less attractive alternatives available here, and experiments have already been made on materials such as Norfolk reeds, bracken, peat, potato and tomato haulms, sunflower stalks, linseed straw, hop waste and hop vines. These, however, vary considerably in their response to treatment, even by chlorination, and although it is possible to make cellulose pulp of a kind from each of them, when this is judged by the resultant criteria of yield, colour, strength and cleanliness, they do not equal weed-free straw; moreover, as a rule they are neither so plentiful nor so easily collected as straw. Nevertheless, they may well serve to supplement straw, particularly in war-time, and some of them by reason of their strength may suitably be used to reinforce straw pulps.

Finally, it may be pointed out that although this concentration on home-produced raw materials is a direct result of war-time conditions, it may well prove to be the foundation of an attempt to render Great Britain permanently independent to a great extent of imported cellulose ; this would, in fact, be no more than to follow a precedent, already set in a similar way in Germany and Italy. If, however, this prospect is to mature, it seems to call for an organized attack on the many and various aspects of the problem involved. Not only are there the technical questions of pulp production outlined above, but bound up with these are matters such as the cultivation of straw containing the minimum quantities of weeds, and of straw which will give the maximum yield of cellulose fibre. The claims of the other uses to which straw is put at present will also have to be taken into account, and in fact the whole matter is obviously very closely bound up with the agricultural policy of the nation.

OBITUARIES

Prof. William Frecheville

WILLIAM FRECHEVILLE, who died on July 30, was born in 1854 at Halifax, Nova Scotia, the son of R. R. F. Frecheville, barrister-at-law. Educated largely in England, he entered the Royal School of Mines in 1871, and in 1875 graduated in mining, metallurgy and geology. From that date until 1889 he held mining appointments abroad in different countries and in various capacities. With this experience he established himself as a consulting engineer in London, where his professional reports were greatly valued by reason of their sound recommendations and his uncompromising integrity. This work again took him to every land and to every sort of mine ; and in 1905 he was elected president of the Institution of Mining and Metallurgy.

It was not surprising, therefore, that in 1912 he was invited to allow his name to go forward for the then vacant chair of mining at the Royal School of Mines, Imperial College of Science and Technology. That he should have accepted this invitation to take up an academic appointment when he might well have continued a successful consulting practice or even have retired was in keeping with his inflexible will to work and his dauntless spirit. With nothing previously prepared and nothing to build upon except his own unassailable experience and his reading, he nevertheless set about and completed in time a series of systematic lectures on the mining subjects which fell to him as head of the department he took over. At the College his natural dignity and unfailing courtesy made him at once acceptable to his colleagues of the professoriate, by whom he was shortly afterwards elected as one of their representatives on the Governing Body.

In his own department Frecheville set himself the unpopular but cleansing task of putting down excessive coaching of students by members of the staff, permitting coaching only where there had been unavoidable absence from the adequate teaching which the College provided and for which the parents of students paid. Carrying on with a diminished staff, and fewer students, during the War of 1914–18, he was there to accommodate the influx of the large number which followed upon demobilization ; until in 1919, having by then a staff of his own selection and seeing one whom he could recommend to take his place, he resigned. In that same year the Institution of Mining and Metallurgy made him an honorary member in acknowledgment of his eminence in the profession and of the public spirit which prompted him to give students the benefit of his ripe experience ; in that year also he was made an emeritus professor of the Imperial College. Two years later he placed the sum of £2,000 at the disposal of the College for initiating research fellowships in mining and metallurgy, all of which was spent in useful awards for such work. Further distinction came when in 1926 he was awarded the Gold Medal of the Institution of Mining and Metallurgy ; and again in 1932 when he was made a fellow of the Imperial College—one of its first fellows.

In private life Prof. Frecheville was the courteous English gentleman. Married in 1890 to Helen, daughter of George Hamilton Penny of Sydenham, he celebrated earlier this year with his wife their golden wedding, the announcement being made in terms expressive of the swift but happy passage of time. Their one great grief was the loss of their only son, an officer in the Royal Engineers, who having fought through the War of 1914–18, went on to fight and to meet his death in Russia. Prof. Frecheville is survived by his widow, five daughters and grandchildren.

S. J. TRUSCOTT.

Major P. H. G. Powell-Cotton

WE regret to record the death of Major P. H. G. Powell-Cotton, zoologist, anthropologist, and one of the best known of big-game hunters in the world, which took place on June 26, at the age of seventy-three.

Percy Horace Gordon Powell-Cotton was born on September 20, 1866. He was educated privately and commissioned in the 5th Battalion the Northumberland Fusiliers, attaining the rank of major before his retirement. The greater part of his life, however, was devoted to travel, big-game hunting, and the collection of zoological specimens and ethnographical objects. The museum which he founded on his estate at Quex Park, Birchington, Kent, was one of the finest private collections in Great Britain, and had he been able to carry out the extensions which he had planned before the outbreak of the War, would probably have been one of the most attractive exhibitions of big game in the world.

For nearly forty years Powell-Cotton was engaged almost continuously in conducting big-game hunting and collecting expeditions. Among the earliest scenes of his activities was Western Tibet, where he travelled on three occasions. In Africa there was scarcely a remote, and in his earlier days little-known, part of the continent which he had not visited. He crossed Somaliland; and in a journey from Mombasa to the White Nile passed by way of Mount Kenya and Mount Elgon, and Turkana and Latuka, when these regions were indeed strange lands. Lado Enclave and Lake Edward were reached through the Ituri forest, and the Cameroons were visited three times; while Tanganyika, Southern Angola and South-West Africa were some only of the scenes of his exploits.

Powell-Cotton's interests were not merely those of a big-game hunter. He was also keenly interested in zoological and anthropological science. In zoology many new species have been associated with his name; and his collections exhibited in the public and private galleries of his museum at Birchington were readily placed at the disposal of students of zoological and ethnographical science. In anthropology, as was shown in his communications to the proceedings of the Royal Anthropological Institute, a profound sympathy with the point of view of the black man did much to compensate by accuracy of observation and understanding for a lack of systematic training. He was deeply interested in primitive arts and crafts and had brought together long series from almost every part of Africa, as well as from Tibet. At the same time he was a generous donor to the collections of the Ethnographical Department of the British Museum. In addition to communications in scientific periodicals, Powell-Cotton was the author of "A Sporting Trip through Abyssinia" and "In Unknown Africa".

CAPTAIN GUY DOLLMAN writes: "I have been a frequent visitor to the Powell-Cotton Museum during the last twenty or thirty years and have witnessed its growth and expansion from a comparatively small collection to the finest private museum in Great Britain; in fact, it would not be an exaggeration to say that this museum is one of the foremost private museums in the world.

"Powell-Cotton specialized in presenting geographical groups of animals in his exhibition galleries and nearly all the specimens exhibited were close on record examples. With the exception of some specimens shot by Mrs. Powell-Cotton and others by the Misses Powell-Cotton, all the exhibits were personally collected by the Major. In the central gallery there is a magnificent group of African game animals, including the largest elephant which has ever been brought out of Africa, and the collection of elephant tusks contains some of the finest of specimens.

"Recently some new groups have been arranged in new galleries and some of these show a gradual transition from marshy surroundings to desert and mountainous environment. Here we have exhibited some of the Nyalas shot during Major Powell-Cotton's fairly recent expedition in south-east Africa. Among the desert animals is the new wild ass collected by Miss Diana Powell-Cotton, to which I gave her name when describing it. In the mountainous series are shown Barbary sheep and African ibex. There are also cases containing a fine group of Asiatic ibex, sheep and goats and others are filled with collections of apes and monkeys, the Cameroon gorilla group being especially noteworthy.

"In addition to the natural history specimens exhibited there is also a very extensive collection of ethnographical material, and quite apart from the exhibition branch of the museum there is a very large study collection which is available to students from all over the world. This has been consulted on many occasions by the principal mammalogists throughout Europe and America, and resulting from the work of these experts the Powell-Cotton Museum is extremely rich in type specimens.

"Of recent years the museum at Quex has become more and more a family affair. The Misses Powell-Cotton, in addition to accompanying their father on some of his trips to the Red Sea Province and Zululand, have also undertaken expeditions of their own into Angola, where considerable additions to the museum were obtained. Powell-Cotton's last two expeditions were to South-West Africa and Tanganyika Territory; on the former trip he was accompanied by his son, and on the latter expedition Mrs. Powell-Cotton did much of the shooting."

WE regret to announce the following deaths:

Mr. W. C. Burnet, secretary to the Delegates of the Local Examinations, University of Oxford, on August 3, aged sixty-three.

Dr. R. Hanitsch, director of the Raffles Museum and Library, Singapore during 1895–1919, on August 11, aged seventy-nine.

Mr. A. H. Howell, senior biologist of the Bureau of Biological Survey of the U.S. Department of Agriculture, an authority on the geographical distribution of mammals and birds, on July 10, aged sixty-eight.

Sir George Macdonald, K.C.B., F.B.A., permanent secretary of the Scottish Education Department during 1922–28, an authority on numismatics and the history of Roman Britain, on August 9, aged seventy-eight.

Sir Daniel Thomas, known for his sociological, educational and antiquarian work in Wales, also for his work in the foundation of the National Library and the National Museum of Wales, on August 8, aged seventy-six.

Prof. N. T. M. Wilsmore, professor of chemistry in the University of Western Australia during 1913–37, formerly assistant professor in University College, London, on June 12, aged seventy-two.

NEWS AND VIEWS

Element 85

It is announced that Dr. W. Minder, of the University of Berne, has succeeded in isolating element 85. This, it is claimed, has been produced in small quantities from the decomposition of actinium, which is radioactive. Dr. Minder has named the new element 'helvetium' in honour of his country. It is hoped that further details of this claim will be available shortly. Commenting on this announcement in the *Evening News* (London) of August 13 is of such encouraging significance as to be worth placing on record. This newspaper says: "It is odd to learn to-day, in the midst of war, that a patient Swiss scientist has succeeded at last in isolating the elusive chemical element '85'. It is still odder to reflect that in the long view of history a discovery of that sort may rank above all the perils and victories of these days."

The Purchase Tax and Literature

It was announced by the Chancellor of the Exchequer in the House of Commons on August 13 that newspapers, books and periodicals are to be exempt from the proposed purchase tax. He stated that he feels it would not be in the public interest at this time of war that there should be any decrease in the circulation of newspapers or any diminution of the services they provide for the public. This announcement will undoubtedly give satisfaction to all scientific workers. There is no doubt, however, as pointed out in the leading article entitled "Books in Wartime" in NATURE of May 11, p. 719, that this welcome decision is of much greater significance than would seem superficially. Sir Kingsley Wood added that books are to be exempt from the tax "at least for the present". It is to be hoped that, for the important reasons set out in the abovementioned article, the future will not bring any significant change in this new policy.

The New World Order

In his Cawthron lecture, 1939, "Some Problems of the New World Order" (Nelson, New Zealand: Cawthron Institute, 1939), Dr. G. H. Scholefield, pointing out that the raw material of political science is man in his organization for life, the family, the community and the nation, where the reactions of mankind are not so well known and precise as in biology or chemistry, gives a brief review of the sources of our liberty, the post-War revolutions and the rise of the dictatorships. Tracing the growth of German aggression, he emphasizes that with the destruction of dictatorship, the problem of settling Germany in a peaceful and prosperous state will remain and will involve some sacrifice. The great danger in such a war as this is that it may end before our leaders have fully studied how best to make peace and how to arrange international relations in future. This will involve attention to economic matters and the solution of problems of social organization.

Science and invention should alleviate man's labour, enable him to maintain himself by working shorter hours and to devote a greater proportion of his time to rest, to pleasure and to cultivating the arts. Failure of the social sciences to keep pace with the applied sciences has led to the position that the human race can produce all that is required for its material well-being with quite a light amount of personal labour while we have not devised means for all potential consumers to obtain possession legally of what they require. Neither Germany nor the democracies have solved the problem of absorbing unemployment and bringing mechanization under social control. Finally, Dr. Scholefield briefly touches on the possibilities of an international federation of States.

India's Future and the Constitution

Once again the British Government, notwithstanding the preoccupations of war, has turned aside to direct its attention to furthering the interests and promoting the welfare of a people for whom it accepts imperial responsibility. The statement of policy made by Lord Linlithgow, Viceroy of India, on August 9 and by Mr. L. S. Amery, Secretary of State for India, on the same day in the House of Commons was framed with the object of enabling the people of India to fulfil their anxious desire to contribute fully to the common cause in the present world struggle, and to ensure the triumph of our common ideals. In brief, the British Government proposes in the interests of Indian national unity, and notwithstanding the differences between parties which previous discussion has shown to be still unbridged, that the Viceroy's Council should now be expanded to include representatives of the political parties, and further that a consultative committee should be established which, as a war advisory council, will meet at regular intervals and will include representatives of the Indian States and of other interests in the national life of India as a whole. The statement of policy goes on to say that while it is clear that the present moment when the Commonwealth is engaged in a struggle for existence is not one in which fundamental constitutional issues can be decisively resolved, yet the British Government is prepared to undertake to set up at the close of the war a body representative of the principal elements of India's national life in order to devise the framework of a new constitution.

The state of tension between the various elements of the political situation in India at the present time is too well known to need stress. It has led to a deadlock, and lays it open to doubt whether the democratic idea has obtained a more than superficial acceptance in the minds of powerful sections of the

Indian population. The British Government is not blind to this aspect of the situation. While making it clear that Dominion status is its objective, it has laid it down without ambiguity in this statement of policy that the British Government cannot be a party to the coercion of any elements of India's national life into obedience to a system of government whose authority those elements do not accept. Secondly, it is declared categorically and insistently that the framework of the scheme for the future government of India should be primarily the responsibility of Indians themselves, and should originate from Indian conceptions of the social, economic, and political structure of Indian life. Subject to responsibilities from which His Majesty's Government cannot divest itself, it desires to see Indian conceptions given the fullest expression. This statement of policy made on behalf of His Majesty's Government is a bold and timely step forward to promote national unity among the Indian peoples. Its success or failure depends upon the people themselves. For while it embodies those principles of social justice which would submit the form of government to the determination of the peoples themselves, its translations into practical effect is clearly made to depend upon the display of that spirit of toleration, the exercise of that mutual co-operation, and that freedom from coercion which is the essence of the democratic ideal.

Colour-Blindness and Camouflage

THE chief characteristic which distinguishes colour-blind people from those with normal vision, is a reduced ability to distinguish colours that are normally quite distinct. Superficially, therefore, it would seem highly improbable that colour-blind persons could detect a camouflaged building that an ordinary observer would miss. This suggestion, however, which has come from the United States recently, is not wholly without foundation, as there are at least three ways in which certain colour-blind observers might see more than the ordinary person. For example, in a building camouflaged with large irregular patches of colour, the actual outline of the building may be lost in the jumble of these patterns. But the colour-blind person may be scarcely conscious of the variegated colours, so that to him the outline of the building may be almost unaffected by the camouflage. In the Ishihara test for colour-blindness, certain of the cards actually use this principle ; a faint blue figure is printed on a background of highly coloured dots of various hues. To the normal observer the blue figure is lost against the background, but the colour-blind person may spot it. Again, in the protanopic and protanomalous type of defect, reds and yellows appear darker than usual, and with certain colouring of building and background this could lead to an enhanced contrast and so give the colour-blind person his advantage.

That a third very hypothetical case is possible, is shown by the fact that, using a colorimeter, it is possible for a normal observer to make a colour match between two halves of a field that would not be a match for a defective observer of the anomalous trichromat type. It could therefore be argued that it might happen that a building matched its background for the normal person, yet, for the anomalous trichromat, the two would be distinct. But for every instance of this kind that might be suggested, there are innumerable examples in which the colour-blind observer is at a marked disadvantage, and in other ways would of course be a source of real danger. Moreover, if the normal person were provided with pieces of coloured glass, it would be most unlikely that the colour-blind person would ever be able to score off him.

University of London

THE report of the Principal on the Work of the University of London, 1939–40, gives a short account of the officially recommended dispersal of the various schools. The result was a heavy demand on those who received the evacuees, the Universities of Cambridge, Bristol and Wales in particular. The intensive air-raids which were expected not having yet arrived, Birkbeck College has re-opened for day and evening classes. The Imperial College of Science and Technology has remained open at South Kensington for several courses in chemistry, physics, and mining, and the London School of Economics with day teaching at Peterhouse has maintained evening classes in London. Bedford College went to Newnham, and Westfield to St. Peter's Hall, Oxford. The agricultural students at Wye went to Reading for the first term, but the College was re-opened for teaching last January. The British Postgraduate Medical School and the Lister Institute remained in London, and nearly all the other medical schools are now there again, and would plainly lose by dissociation from their special hospitals. The Government decision not to call up under the age of twenty led to some trouble in unexpected accommodation. At the end of August the Ministry of Information took over the Senate House, and the new wing designed for the Institute of Historical Research, when finished, will also be occupied by the Ministry. The University was due to receive a grant of £25,000 from the National Fitness Council towards the new Students' Union, but that was vetoed by the Treasury on the outbreak of War. Lord Nuffield gave twice as much, and on being asked if in the altered circumstances he would withdraw the gift, wished it to be retained for building in happier times.

It is good to learn that the work of the University goes on satisfactorily. Examinations have been held in eleven provincial centres, and there has been no lowering of standards. The University has had to provide for a large number of external students, and the Extension Department has made up for the falling off of its normal work by attending to the education of British and Canadian soldiers. The War will reduce the supply of students, though the numbers at present keep up rather well, so that the question of adequate financing will become urgent. The decision not to reduce the Government grant is important. That of the L.C.C. for this year is much less, but other contributing bodies, we are glad to see, continue their support as usual. The Senate has wisely decided to retain its Publication Fund for works of science and learning on the scale which funds allow. Grants amounting to £1,583 were made last session. Among the benefactions we notice £25,000 in seven annual instalments for rebuilding at Queen Mary College from an anonymous donor, £2,660 from the Duke of Bedford for a fellowship in medical radiology at the Middlesex Hospital Medical School, a donation of £250 for one year from the Iraq Petroleum Company converted to twice as much for seven years, and £250 a year for seven years from the Gaekwar of Baroda to make a lectureship in Marathi a full-time post.

Pioneering in Educational Radio

Dr. C. G. Abbot, secretary of the Smithsonian Institution, has announced that a period of four years of pioneering in educational radio was completed on June 9 by the Institution. The object was to increase and diffuse knowledge among the people generally. The title of the popular series of broadcasts was "The World is Yours". In addition to science, the main theme of the series, the broadcasts dealt with exploration, history, engineering and invention, and art. A few recent titles will show the wide diversity of subjects treated: "Stars in the Sky", "The Indians who met Columbus", "Earthquakes", "Flying in Safety", "Cortez, the Conquistador", "Pompeii Lives Again", "Radium", "Dinosaurs". Since the programme was inaugurated on June 7, 1936, "The World is Yours" has expanded from its original 27 stations to a network of 82 stations covering the United States. The most recent, and the highest tribute paid to the series came last February when a leading American radio audience research service announced that the Smithsonian dramatizations received the highest rating of all serial programmes on the air. This followed from an analytical survey of all the programmes given on all networks.

To promote further this 'increase and diffusion of knowledge', the educational value of these programmes is preserved by the Educational Radio Script Exchange, U.S. Office of Education, Federal Security Agency. Hundreds of school and civic groups have used these scripts for production by radio and over sound systems. Another new radio service began last October with the inauguration of *The World is Yours Magazine*. Dedicated to the popular theme, "catch it by radio—fix it in print", these weekly magazines present a wide variety of articles by Smithsonian curators on historical, scientific, and engineering subjects for lay readers and schools. Some of the features of these new 'doors' to knowledge are dramatic scenes from the script, selected bibliographies for further study, recent news from the Smithsonian, and illustrations from rare drawings and photographs in the files of the Institution. Nearly 100,000 copies of these have been sold in the first half-year, the sales being on a non-profit basis. "The World is Yours" is produced for the Smithsonian Institution by the U.S. Office of Education with the co-operation of the National Broadcasting Company and with the assistance of the Work Projects Administration.

Regulation of the Upper Mississippi

The Mississippi and Missouri, together, form the longest river system in the world, extending to a length of 4,502 miles. Above its junction with the Missouri, the Mississippi has a length of 1,170 miles and drains an area of 171,500 square miles. In an article in *Engineering* of July 19, a description is given of that part of the Upper Mississippi lying between the Missouri and the town of Minneapolis in Minnesota, 659 miles long. In 1907, a project was adopted for the regulation and improvement of the river from Missouri to Minneapolis in order to provide a 6-ft. channel at times of minimum flow. The work carried out consisted mainly of dredging and the construction of wing dams to restrict the width of the low-water channel. Twenty years later, the U.S. Congress directed that a survey of the river should be taken with the view of providing a low-water channel with a depth of nine feet. The project involved the construction of a series of locks and dams, and fairly extensive dredging. The work was completed last March at a cost of 170 million dollars. Twenty-five dams were required, and special Tainter and Roller gates were used for regulating the flow. The gates of later construction are designed so that they can be lowered several feet below the normal level of the pool, allowing even heavy ice to pass over the top.

The principal traffic on the Upper Mississippi River consists of fleets of barges, usually pushed by steamers of the stern-wheel or twin-screw type. The barges range in length from 100 ft. to 300 ft. and in beam from 24 ft. to 48 ft. The capacity varies from 500 to 3,000 tons. A tow of barges, practically filling one of the 110 ft. by 600 ft. locks, carries 6,000–8,000 tons of goods, and requires a 1,000 h.-p. steamer for its propulsion. In operation, it is possible to pass about fifty fleets of barges through the locks in twenty-four hours. The fifty-two over-bridges between Minneapolis and the Missouri River in general provide vertical clearances above high water in excess of 50 ft. and horizontal clearances varying from 106 ft. to 710 ft. Traffic on the river consists mainly of coal, petrol, fuel oil, steel-products and grain. The total tonnage handled between Minneapolis and the Missouri in 1936 was 2,300,000 tons.

Strengths of Indian Timbers

Ever since the inauguration of the Imperial Forest Institute at Dehra Dun, one of its branches has been engaged in testing out the strength and properties of indigenous timbers. Many timbers hitherto neglected or regarded as useless for practical commercial purposes are now coming under the tests of the research investigators. The Timber Testing Section of the Forest Research Institute has been studying the strength properties of Indian timbers for many years now, and more than 215 consignments of timber have been tested up to date. In *Indian Forest Records*, (*Utilization*) 1, A (Govt. of India Press, New Delhi 1939), Mr. V. D. Limaye gives authentic information, on the possible uses and comparative strengths of thirty-six common Indian timbers and of six commonly imported timbers (three of which come from Burma) of different genera and species. This demonstrates the wealth of fine timbers there are in India. Yet three quarters of a century ago or less the bulk of the population in India, including the British, relied chiefly on three timbers only, according to situation—teak, sal (Shorea) and deodar.

Meteorology of the Australasian Antarctic Expedition

THE Australasian Antarctic Expedition of 1911–14 under the leadership of Sir Douglas Mawson seems an episode of the remote past, for so many better equipped expeditions have intervened. The latest of the scientific reports of this expedition is the fifth of the series and is in three parts (Australasian Antarctic Expedition, 1911–14. Scientific Reports. Series B, Vol. 5: Meteorology. Part 1: Records of the Queen Mary Land Station; Part 2: Meteorological Log of the S.Y. "Aurora"; Part 3: Sledge Journey Weather Records; Appendix, Macquarie Island Weather Notes for 1909–1910–1911. Pp. x+282+4 plates. Sydney: Government Printer, 1940. 40*s*.). It is concerned with meteorology. Part 1 of this volume deals with the records of the Queen Mary Land station—the 'Grottoes'—in latitude 66° S., longitude 95° E.; Part 2 covers the meteorological log of the S.Y. *Aurora*, and Part 3 the weather records of the sledge journeys; an appendix includes the daily weather records made at Macquarie Island by Otto Bauer's sealing party from August 1909 to July 25, 1910, and January 1 to December 12, 1911.

Although the report is largely statistical, there are some excellently reproduced photographs, at the end of the volume, of scenes of meteorological interest. Four of these show characteristic features of the edge of the Antarctic Continent that must, judging from the descriptions of others who have written about the same subject, be very typical. Thus, in Plate 4, Fig. 2, a canopy of strato-cumulus cloud is seen over Commonwealth Bay, with cloudless sky over the continent to the south. It is a scene of peace and beauty, the ripples in the sea showing that there was only a light westerly wind blowing. In Plate 3, Fig. 1, the sky is still partly cloud-free; but the clouds look like alto-cumulus and the horizon is a dark smudge indicating the approach of a blizzard. In Plate 4, Fig. 1, a sledging party on the plateau interior of Adelie Land appears to be preparing to weather a blizzard that is presaged by dense masses of cirrus cloud. The sequence is completed by Plate 2, Fig. 2, in which cumulo-nimbus clouds are breaking up just after a blizzard north of the Mertz Glacier Tongue. The bulk of the volume consists of undiscussed meteorological tables, but a footnote to p. 16 says that "Dr. E. Kidson has been engaged preparing two volumes analysing and discussing the Expedition's meteorological data. This will be published in due course".

Epidemiology in the Army

IN a recent article (*Ann. Int. Med.*, 13, 2229; 1940) Lieut.-Colonel J. S. Simmons, of the Medical Corps of the United States Army, divides the hazards of military life into three groups according as they arise in peace-time service, during mobilization or in actual warfare. In peace-time the soldier's life is as safe as, if not safer than, the civilian's, as he has been carefully selected, housed in modern barracks, fed on a balanced diet of wholesome food and forced to take adequate exercise. He is trained in physical hygiene, and his health is under medical supervision. During mobilization, though efforts are made to continue existing medical facilities, the rapid accumulation of susceptible recruits from all parts of the country frequently results in epidemics. In actual warfare, the soldier is not only faced with the risk of injury and death from battle, but is also exposed to infection. Between April 1917 and December 1919 when the United States Army was engaged in that War the casualties from all quarters were 50,000 deaths due to battle and 58,000 deaths caused by disease. The principal diseases to which the soldier is exposed during mobilization and war are wound infections, the morbidity and mortality of which have undergone a striking decrease since the introduction of antiseptic surgery, gastro-intestinal infections due to contaminated food and drink, including enteric fever, dysentery and cholera, venereal infections, the admission rate for which in the United States Army was 87 per 1,000, respiratory infections, including influenza, pneumonia, scarlet fever, diphtheria, measles, mumps and cerebrospinal fever, and insect-borne infections, such as malaria, yellow fever, typhus and plague.

History of Blood Transfusion

IN a recent thesis (*Thèse de Paris* 1940, No. 344) on this subject, Dr. Edmond Ecale states that the history of the transfusion of blood is intimately connected with the discovery of the circulation. Although even in the prehistoric period the idea of the operation had been conceived, it was in the country of Harvey that the first scientific attempts of transfusion were made, namely, by Christopher Wren in 1656 and Edmund King in 1667. Jean Denis was the first to carry out transfusion from an animal to man in 1667, and was followed a few months later by Richard Lower in England, Riva in Italy and Kaufmann in Germany. Transfusion of blood was prohibited by the Châtelet edict in 1668, and almost fell into oblivion for nearly a century and a half. The first successful transfusion of blood from man to man, which was carried out by the obstetrician James Blundell in 1825, marked an important progress in the history of the method, and was performed with a syringe containing defibrinated blood to prevent coagulation. The introduction, however, in 1879 of intravenous injection of normal saline which was a simpler and safer method interfered with the progress of transfusion of blood for some time. After the beginning of the twentieth century, transfusion of blood was again revived on the discovery of agglutinins, iso-agglutinins, blood groups and blood incompatibilities, which enabled a correct choice to be made of donors and recipients, while the use of anti-coagulants, paraffined tubes and other refinements of technique led to the adoption of the perfected method employed at the present time.

The Long-term Prisoner

In a paper read before the ninety-fifth meeting of the American Psychiatric Association (*Amer. J. Psychiat.*, **96**, 1321 ; 1940) Dr. Marvin Sukov records his observations on thirty men completing life sentences in the Joliet-Stateville branch of the Illinois State Penitentiary. Their ages on admission ranged between 16 and 49, and their ages on examination were between 39 and 73. The study was conducted by means of a questionary in which each inmate was individually interviewed for a period averaging 1¼ hours. Dr. Sukov's conclusions were as follows: (1) Imprisonment was accompanied by progressive social severance, shown by progressive diminution in visits and correspondence in every case. (2) The patients' basic interests with regard to religion, crime and intellectual sphere were little modified by years of imprisonment. None expressed a reduction in alertness except those advanced in age, who attributed it to that cause. (3) Twenty-five who admitted their guilt stated that they had deserved punishment but that their punishment was too severe. (4) While all had a desire for freedom, many had become resigned to life imprisonment and without help would probably be unable to make an extramural adjustment. (5) Nearly all after many years imprisonment showed no antagonism to society, but none could point to a single individual as a friend.

Cave Worship

In an interesting article in the April issue of the *Hibbert Journal*, Dr. R. R. Marett remarks that in addition to its mystic and religious associations the cave played no small part in early medicine, and suggests that it was primarily as a hydropathic establishment that the cave found so much favour with the sick. In the cave of Aesculapius, mentioned by Pausanias, for example, the healing waters gushed out from a rock, and at Elis in the cave of the Anigrid nymphs he states that a leper must sacrifice before bathing in the neighbouring river in order to leave his "shame" there. There were also caves mentioned by Pausanias of which the efficacy had possibly nothing to do with water, such as the cave of Aphrodite. Moreover, the famous Lemnian earth or terra sigillata which was supposed to provide an antidote to snake-poisoning was obtained from a cave.

The Government Museum, Madras

Under the superintendence of Dr. F. H. Gravely, an important extension to the Government Museum, Madras, has been completed and opened to the public, following the plans of the late R. Dann, consulting architect to that Government. The new building has provided accommodation for the staff of curators, the block which they formerly occupied being now given up to the zoological collections. But its main function is to give suitable expression to the evolution of the decorative motives of the architecture of the magnificent temples of South India. For the Tamil country, these changes form an interesting and logical sequence. The temples of other parts of India differ from those of Tamil origin, and although the development of their architecture is not yet fully understood, attempts have been made in the new building to indicate the succession of changes. A short account of these arrangements, based upon Dr. Gravely's address at the opening ceremony, which was performed by His Excellency the Governor of Madras, Lord Erskine, appears in the July number of the *Museums Journal* (40, 109 ; 1940).

Nematode Parasites of Plants

A catalogue of nematode parasites of plants, compiled by Dr. T. Goodey has been issued by the Imperial Bureau of Agricultural Parasitology, St. Albans, price 10*s*. The work consists of an alphabetical list of the scientific names of all plants which have been reported as hosts of nematodes, comprising more than 2,000 species and varieties of flowering plants, 78 ferns, 55 mosses, 5 liverworts and 3 seaweeds. In each case the appropriate parasite or parasites is stated, together with the name of the first recorder and the date of the record. For convenience, an alphabetical list of the popular plant names, with the scientific name appended, is also supplied, so that the reader can be sure of finding the information he requires by whichever plant name is the more familiar to him. The publication concludes with a list of references relevant to the records cited. Usually this is the earliest record obtainable, but in a few cases a more accessible reference has been deliberately selected.

Announcements

The Home Secretary has announced in the House of Commons that he is willing to consider steps to enable alien men of science who are not released to carry on their scientific activities or studies in internment.

The following appointments in the Colonial Service have recently been made: F. R. Bell, veterinary officer, Uganda ; J. H. Hughes, assistant conservator of forests, British Guiana ; R. M. Shackleton, geologist (temporary), Kenya.

A further step in the mobilization of the man-power of Great Britain is marked by the issue of the first industrial registration order made by the Minister of Labour. Registers have already been made of professional engineers, chemists and physicists and quantity surveyors. The new order requires the registration of skilled men more than twenty-one years old in certain specified occupations, mainly engineering, who are not employed on Government work. The five days of registration, to which also the test of full employment on Government work applies, are August 19–23.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Planning the Peace

THE excellent series of articles which have been published in NATURE on the applications of science to social problems encourages me to suggest that specific efforts should be made for planning the peace. It may seem to be an inappropriate time to embark upon this project. I have no wish to distract the attention of those who are actively engaged in the prosecution of the War; but there are others who, by reason of age, physical infirmity, and so on, are doomed to relative inaction. Many such, by virtue of special training, experience, good judgment, and brilliant intellect, might well be encouraged to collaborate in drawing up some indications of the lines which should be followed in the light of their knowledge and appreciation of the grievous errors of the past. At the present time, feelings run high, and the irrational impulses of mob psychology are no sound guide to either the conduct of the War or the making of the peace. It is all the more desirable, therefore, that the restraining influence of level-headed advisers should be marshalled in the interests of sanity.

Presuming that Great Britain emerges successful from the contest, the War will be won; for the demagogic autocracies of Germany and Italy contain within them the seeds of their own destruction, and there can be little doubt that public opinion in the Americas is gradually becoming convinced that the security of the States and the survival of liberty depend upon the victory of Great Britain. It has indeed long been the opinion of many that the survival of civilization, that is, of a corporate life founded on a basis of mutual goodwill, freedom of thought, and Christian ethics, depends upon the co-operation of the English-speaking peoples.

The problems to be considered are of the greatest variety and complexity. The effects of the Treaty of Versailles and the drift into war have demonstrated the blindness of our statesmen to the most elementary facts of individual and social psychology. The psychologist with a biological training is best fitted to explain the causes of war, of which the most fundamental are unhappiness and a sense of grievance. There can be no doubt that there will be a profound change in economic conditions after the War. We may look forward with satisfaction to the abolition of gross disparities in individual incomes; but the levelling process demands the most minute care to avoid the dangers of a communistic revolution. The recent admirable broadcast by the Right Hon. R. A. Butler exemplifies the help which we may expect to receive from the historian and the diplomatist.

Probably the best method of attacking the problem at the present time would be by a series of articles by selected authorities to be published in NATURE or elsewhere.

Identification and Determination of Aromatic Compounds in Mineral Oils

OUT of the many methods suggested[1] for the quantitative determination of the total of aromatic constituents in mineral oils, none is suitable for giving information about the nature of these constituents. In recent systematic research[2] on the aromatization of aliphatic compounds, the method of side-chain oxidation has been used, which, however, is only of value if the number of carbon atoms in the side-chains is known and is not applicable to the fundamental hydrocarbons like anthracene, phenanthrene, naphthalene or benzene.

Ultra-violet spectrography provides an easy method of identifying and determining quantitatively aromatic hydrocarbons in a mixture with substances which show no selective absorption at all, or at least not in the same region as the aromatic hydrocarbons. For the following fundamental hydrocarbons, absorption bands exist which are characteristic, and the intensity of which is directly proportional to the concentration of the hydrocarbons: benzene, toluene, xylene, naphthalene, phenanthrene, anthracene. The bands to be used for their identification are listed in Table 1. The method may be only of limited value in two instances: dialkylbenzenes with identical positions of the alkyl groups but substituted with different alkyls may be indistinguishable; and alkylated polycyclics may exhibit spectra practically identical with those of the parent hydrocarbons. Apart from this limitation, we have been able to identify all the absorption bands observed for those fractions of Iraq petroleum and of a shale-oil of Palestinian origin which distil up to 200° at 0·1 mm. pressure with the bands of the above six hydrocarbons, so that no other constituents of aromatic character are present.

For the quantitative determination of these hydrocarbons, the intensity of the characteristic absorption bands for a given sample is compared, visually or by means of a microphotometer, with the intensity of the same bands for the standard substances in known concentrations. For these comparisons, the substances are either used in solution in (non-absorbent) light petroleum or in the gas phase. With this method, the following figures have been found

TABLE 1.

Benzene	2433,2375 A.
Toluene	2700
Xylene	2713,2739
Naphthalene	3100
Phenanthrene	2932
Anthracene	3570,3760

TABLE 2 (Iraq petroleum).

Benzene content	0·02 per cent
Toluene	0·31
Xylene	0·52
Naphthalene	0·30
Phenanthrene	1·36
Anthracene	1·76

TABLE 3 (Shale-oil)

Benzene content	0·16 per cent
Toluene	0·18
Xylene	3·20
Naphthalene	4·60
Phenanthrene	1·80
Anthracene	1·60

in the case of Iraq petroleum (Table 2) and of the Palestinian shale-oil (Table 3).

The usefulness of the method is evident. It gave information about the interesting phenomenon of azeotropic distillation of aliphatic and aromatic hydrocarbons, which will be studied in greater detail at a later date, and about the aromatization involved in cracking experiments. It may also be noted that the spectrographic method may well contribute to the elucidation of the structure of lubricating oils, which are assumed to be alkylated and partly hydrogenated polycyclic ring-systems; in many cases, dehydrogenation previous to the spectrographic investigation, seems to be useful.

A Patterson Analysis derived from the Cyclol C_2 Skeleton

I AM grateful to Dr. D. Wrinch for pointing out an error in my previous communication on this subject with Dr. Fankuchen[1]. A check of the calculations showed that our previous Fig. 3 was, in fact, derived from an arrangement of the cyclol molecules with a tilt of 36°, as Dr. Wrinch states[2], and not with a tilt of 6° as we had, by an unfortunate misunderstanding, assumed. This arose from a wrong choice of reference line to define the tilt, suggested, although certainly quite unjustifiably, by Dr. Wrinch's original packing diagram.

I have therefore recalculated numerically the Patterson map obtained by placing the cyclols in the insulin unit-cell with a tilt of 6°, and the essential part of the resulting contour diagram, namely, the triangle between origin peaks, is shown in Fig. 1. The only peak in the field is the large diffuse peak *A*, while *B* is a region of low density. The agreement with the experimentally derived basal Patterson projection of Crowfoot[3], which is reproduced in essentials in Fig. 2, is not very close. The low density region *B* compares with the region *C* in Crowfoot's diagram, but such a large central peak as *A* is not present in the latter case. The experimentally derived Patterson projection has a trigonal arrangement of three well-defined peaks (*B*) around the centre, corresponding to interatomic vectors of 22 A. in this projection. In so far as the peak *A* in Fig. 1 be considered as compounded of three such 20 A. peaks, then it is clear from the calculation that these are due to vectors between the *sides* of the cyclol fabric, and do not arise from vectors between the 'slits' of the octahedron. Approximate working indicated that this central peak *A* would tend to be resolved with an arbitrary tilt of 10° or so. A calculation with $\alpha = 13°$ showed this resolution to be very small, and this tilt also destroys the *B* region of low density. Small deviations from the tilt of 6° therefore do not better the agreement with Crowfoot's projection, and the map obtained with an extreme tilt of 36° has already been discussed. Another unsatisfactory feature of Fig. 1 is the absence of a defined 10 A. peak corresponding to Crowfoot's peak *A*, and a strong 10 A. spacing is a characteristic property of most proteins. I therefore consider that this new derived Patterson analysis is not in nearly sufficient agreement with the experimental data for insulin to afford evidence in favour of the cyclol hypothesis.

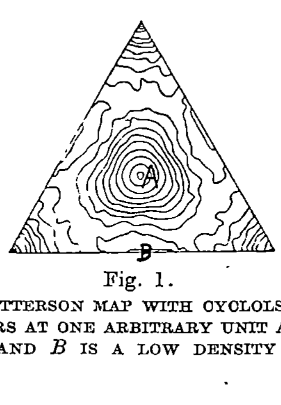

Fig. 1.

DERIVED PATTERSON MAP WITH CYCLOLS AT TILT OF 6°. CONTOURS AT ONE ARBITRARY UNIT APART. *A* IS A PEAK AND *B* IS A LOW DENSITY REGION.

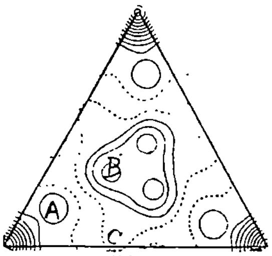

Fig. 2.

EXPERIMENTALLY DERIVED BASAL PATTERSON PROJECTION FOR INSULIN (AFTER CROWFOOT).

In conclusion, I should like to point out that Dr. Fankuchen and myself have never claimed "to have disproved the structure C_2 predicted for the insulin molecule". We were concerned only with investigating the claims by Wrinch and Langmuir[4] of the confirmation of the cyclol hypothesis in the case of insulin by the X-ray data. The work done clearly showed that their primary assumption of approximating the cyclol C_2 molecule by an octahedral arrangement of scattering masses situated at the 'slits' of the cyclol fabric was not even approximately justified. Logically, therefore, their argument was invalidated even without Bernal's criticism[5] or without consideration of the second part of our previous paper or of this communication. I appreciate Dr. Wrinch's criticism of our work on the grounds that only the carbon and nitrogen atoms of the skeleton were considered. Reasons why this should not affect the general validity of the work were given in our paper. In circumstances other than those obtaining at present, it would undoubtedly be most desirable to recalculate the Patterson map having included the oxygen and C_β atoms, in order to settle the matter. In the meanwhile, I would enter a plea for this detailed type of working in comparing any proposed models of protein molecules with the X-ray data, otherwise it is often difficult to separate evidence from speculation.

The Generalized Kaleidoscope

A RECENT communication from Sidney Melmore[1] has refuted my statement[2] "that a kaleidoscope cannot have more than six mirrors". The statement should be "that any kaleidoscope is effectively equivalent to one having at most six mirrors". In the case of Melmore's octahedral kaleidoscope, every pattern produced is symmetrical about either of the planes which bisects the dihedral angles of 120°. Hence two extra mirrors may be placed in those positions without affecting the pattern. Six of the eight original mirrors then become superfluous, and we are left with the four faces of the tetragonal bisphenoid[3] *AB'CD'*. The rectangle *BB'D'D* is one half of the common base of Melmore's two square pyramids, with apices *A* and *C*; hence *E* (the mid-point of *AC*) is the point-object which gives rise to the solid tessellation of cuboctahedra and octahedra.

Op. cit., 159.

I AGREE with Prof. Coxeter's conclusion that no more than six mirrors need be used to produce the solid tessellations. It is now clear that two of his tetragonal bisphenoids, interpenetrating, bear the same relation to my octahedron which two interpenetrating regular tetrahedra bear to the regular octahedron.

Growth of Aggregates in Suspensions

ON reading through the D.S.I.R. report of the Water Pollution Research Board for the year ended June 30, 1938, I was much interested to notice the account of the settling of silt in estuarial waters of the River Mersey. In the course of a study of the effect of sewage upon the rate of sedimentation of mud, it was found (p. 49) that sedimentation occurred only at slack water. The scour during the ebb and flow of the tide erodes fine particles from the bottom so that they disperse more or less uniformly in the water. During slack water, practically the whole of the suspended matter is deposited. It was found that large, fragile aggregates form and then settle at a rate of about 0·011 ft. per sec.

I find that this is approximately the maximum velocity at which these particles obey Stokes's law, that is to say, the settling occurs at the point at which the flow round the aggregate ceases to be wholly streamline. Thus it appears that the mechanism of such settling is that the aggregates continue to grow until their falling speed increases to the point at which the flow becomes turbulent. This prevents further increase of size, so that when full grown their falling speed will be substantially constant.

Radiation and 'Stuffiness'

IN discussing the spectral transmission of human stratum corneum[1], Messrs. Yarnold and Kirkpatrick have overlooked the measurements of Pearson and Norris[2] which show only a very faint suggestion of the absorption band at 4·1–4·2 μ to which they refer.

In connexion with Yarnold and Kirkpatrick's work on the effect of spectral distribution on the comfort of radiant heat, I may mention that some years ago I measured the time of tolerance of radiation of a fixed intensity falling on a given area of the hand, arm or face, for six subjects. In every case the emission from a 'bright' source such as an ordinary gas fire was tolerated considerably longer than an equal intensity from a box kept at barely visible red heat and filled with coal gas flame.

Depression of Neuro-Muscular Transmission in a Crab by Phenothiazine

SINCE phenothiazine is a new and valuable vermifuge, its effect on animal tissues is of some general interest. Its effect on crustacean neuro-muscular function can readily be observed in the shore crab (*Carcinus mœnas*), from which the nerve-muscle preparation is one of the most readily obtainable among invertebrates.

The transmission of excitation from nerve to muscle in the walking leg of the shore crab is characterized by the existence of a natural 'block' at the

a, Perfusion with crab's Ringer; *b*, 18 min. after perfusion with 1 part in 5,000,000 phenothiazine; *c*, 11 min. after perfusion with 1 part in 2,000,000 phenothiazine; *d*, 35 min. after return to crab's Ringer.

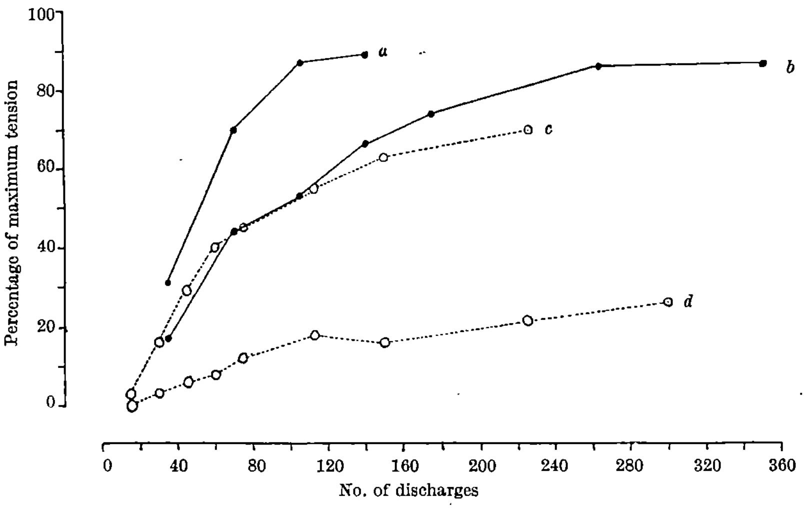

Fig. 2.

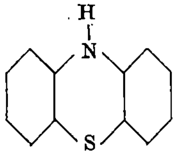
PERCENTAGE OF MAXIMUM ISOMETRIC TENSION DEVELOPED AFTER A GIVEN NUMBER OF SHOCKS.

a, perfused with crab's Ringer; 175 shocks per sec.: *b*, perfused with 1 in 1,500,000 phenothiazine; 175 shocks per sec.: *c*, perfused with crab's Ringer; 75 shocks per sec.: *d*, perfused with 1 in 1,500,000 phenothiazine; 75 shocks per sec.

junction, which can be overcome by the summation of nerve impulses arriving there. A just visible contraction of the flexor muscle of the dactylopodite of the walking leg is observed when impulses arrive at the nerve-muscle junction at a frequency of about 10 per sec., while a maximal contraction is obtained at a frequency of about 300 impulses per sec.[1]

Katz has reported that curare does not prevent transmission across the nerve-muscle junction of Carcinus[2]. Increase of junctional 'block' can, however, be effected by concentrations as low as 1 part in 10,000,000 of the vermifuge phenothiazine:



The extent to which junctional transmission is depressed after treatment with a drug can be assessed from several characteristics of the preparation. In the experiments reported here, the nerve was stimulated with a series of brief condenser discharges through a neon lamp. A number of different frequencies of stimulation ranging between 75 and 175 discharges per sec. were employed and the stimulation was applied for measured periods of time. The tensions developed by the muscle were recorded by a spring lever. An indication of the extent to which junctional transmission is depressed after perfusion of the limb with phenothiazine in comparison with the condition when the limb is perfused with crab's Ringer solution can be obtained from a study of the tensions of muscular response at each frequency and duration of stimulation. If neuro-muscular function in the isolated walking leg of Carcinus perfused with low concentrations of phenothiazine (1 part in 1,500,000 to 1 part in 10,000,000) is compared with that in the limb perfused with crab's Ringer solution, it is found that:

(1) The threshold potential for excitation of the nerve is raised.

(2) The maximum tension obtainable from the flexor muscle of the dactylopodite by stimulation of the nerve at high frequency for an indefinite period is little reduced.

(3) Junctional transmission is depressed. If the stimulation is applied for a constant period of time then, during perfusion with solutions containing phenothiazine, a higher frequency of condenser discharge is required to evoke a given tension of muscular response (Fig. 1). If the frequency of discharge is kept constant, then a greater number of discharges is required to evoke a given tension (Fig. 2). The relative extent to which tension is reduced by phenothiazine, moreover, declines as the range of frequencies is ascended (Figs. 1 and 2). The effect of phenothiazine on junctional transmission is partially reversible.

The sample of phenothiazine was kindly given to me by Imperial Chemical Industries, Ltd.

Mixed Radioactive Indicators in Physiological Experiments

OBJECTIONS have been raised against the use of radioactive indicators in physiology, suggesting two sources of error, namely, a discriminating effect for isotopic atoms, and a change in the behaviour of organic material through irradiation[1]. Although one has good theoretical reasons to believe that the radioactive tracer atoms and their non-active isotopes show the same physico-chemical behaviour[2], and that effects of irradiation could be neglected so long as the specimens are not too active[3], it has been emphasized[2] that doubts about the tracer method can only be removed by experimental evidence.

The property of biological material of discriminating between the radioactive and non-active isotopic atoms represents only a special case of the separation effect of ordinary isotopes in biological tissue[4,5]. This question could be easily examined, in some cases at least, by the use of two or more active isotopes of the same element. If the proportion of these before and after the experiment were the same, then no isotope separation can have taken place. On the other hand, any differentiation can be measured quantitatively. This is only possible with some elements, and is unfortunately not possible with the biologically important phosphorus and sodium, but the general question of biological separation could be accurately investigated with such elements as calcium, iodine, bromine, silver, etc.[6]

The effect of irradiation on tissues could be examined by observation of the amounts absorbed of a solution activated with a suitable tracer element, before and after exposure to the same solution 'tagged' with a different active isotope.

Influence of Combined Phosphoric Acid on the Swelling of Granular Starch

IN some starches phosphorus occurs in combination as a salt of an amylomonophosphoric ester[1],

$$\mathrm{St{-}O{-}PO}\begin{matrix}\diagup OR_1\\ \diagdown OR_2\end{matrix}$$

, where St is a glucose unit in the polysaccharide chain and R_1 and R_2 are metal or hydrogen atoms; in others the phosphorus is not combined with the starch, and part of the phosphorus-containing impurity can be removed by extraction with methanol or cold dilute mineral acid. Potato and wheat starch are representative of the two classes[1].

The metal combined with the phosphorus in potato starch can be varied by washing with appropriate salt solutions and then with water until the filtrate is free from electrolyte[2]. The properties of the washed starch vary with the identity and amount of the combined metal; for example, the swelling capacity of the granules in hot water and the viscosity of the hot 3 per cent paste of a sodium starch are greater than those of the corresponding calcium starch. The difference is not observed in presence of salt and is probably due to the greater tendency of the sodium to ionize and diffuse into the surrounding water. It was expected that after washing with the same salt solution the swelling behaviour of potato starches would be related to their phosphorus contents provided that their average molecular chain-lengths[3] were the same. No simple correlation has been found, however, in a group of eight starches that satisfy this condition and contain 0·145–0·232 per cent phosphorus pentoxide. The swelling capacities in salt solution of the samples differ considerably so that there may be differences in sub-microscopical structure which mask the effect of the phosphorus on the swelling in pure water.

The phosphorus contents of fractions of uniform granule size separated by elutriation in water from one sample of potato starch increase with decreasing mean radius. The copper-reducing powers, specific viscosities in 30 per cent calcium thiocyanate solution, and the solubilities of the fractions in 0·01 *M* phosphate buffer solution, *p*H 7, are almost identical and the differences in swelling capacity in the same buffer solution are small; it may be concluded, therefore, that their average chain-lengths are the same and that the structure factor is common to all. In distilled water, swelling is much higher than in salt solution, and among the sodium starches prepared from the different fractions the swelling increases three-fold as the phosphorus pentoxide content increases from 0·148 to 0·254 per cent (see accompanying table). These differences in swelling are not due to differences in the ratio volume/surface area of the granules[4], since fractions 1 and 2, differing in average radius but nearly equal in phosphorus content, swell equally.

On the other hand the swelling of the fractions from a wheat starch is independent of granule size, phosphorus content, the salt used in washing, or the presence of salt during swelling. It is therefore evident that esterified phosphoric acid does facilitate the swelling of starch granules to an extent dependent upon its amount, but the effect is manifest only in the absence of free electrolyte and when the average chain-length and the structure of the granules are the same.

	Potato Starch						Wheat Starch

RESEARCH ITEMS

South African Stone Bead Industry

The relative scarcity of the stone bead throughout the world justifies a record of the discovery of serpentine beads by Harold S. Harger on sites in the western Transvaal (*Trans. Roy. Soc. South Africa*, 38, 2 ; 1940). From the collection as a whole it has been possible to describe the entire process of manufacture from beginning to end. The prime factor in the establishment of the industry was the occurrence of a serpentine dyke midway between the factories on Nooitgedacht and Winkelhaak. This region affords abundant evidence of settlements of primitive man of pre-Bantu times. The serpentine beads were found in cleared spaces where native kraals at one time had existed. Old furnace slags, an iron hammer, ornamental stone pendants, gold beads, a steatite mould, pottery, etc., combine to indicate that the industry was established by an early Bantu tribe in pre-European times. The greater part of the material consisted of 108 cylinders ready for boring, 15 were finished ready for use ; and 15 beads of copper and 2 of gold were also found, the occurrence of the last named indicating a Bantu origin. Some much-corroded pieces of iron found on Winkelhaak, when fresh, might have been thin enough to perform the boring. One bead had been bent to take the palm of the hand and facilitate vertical pressure. The procedure adopted in manufacture was to trim the material into cylindrical shape and then saw it in sections—a method followed by Cro-Magnon man in the manufacture of stone beads. The segments were then drilled and smoothed, the ends being ground smooth on a stone to make them lie close. To avoid waste of labour owing to splitting in drilling, stones were sometimes drilled before shaping. While the industry is early and pre-European, it is Bantu and not, properly speaking, Stone Age, as usually understood.

The Fishing Heron

Considerable controversy over the heron's diet has long passed between anglers and fish conservators on one hand, who claimed the large proportion of fish in the bird's menu, and bird protectionists on the other, who brought forward the results of pellet and other investigations which showed a preponderance of frogs, voles and other small waterside vertebrates. The argument will now probably be cleared up following the work of Miss A. Hibert-Ware, of Hilary, Girton, Cambridge, who, with the help of others, has collected 270 pellets from Norfolk, Carmarthenshire, Surrey and Cambridgeshire, and found numerous remains of small vertebrates and insects in them, but only remains of the dace among fish, despite the observations on the abundance of eels and coarse fish brought to the heronry nests. Subsequent studies of the digestion of the heron (*Ibis*, July 1940) suggested that fish figure more prominently in the diet than previous food investigations show, and the strong digestive juices and the soft, non-grinding nature of the gizzard leave little opportunity for remains to be ejected in the food pellets. These pellets were found to be strongly acid when fresh. The chief remains noted in the pellets were moles, water voles and Dyticus and Colymbetes insects. Mammalian food also included small specimens of rabbit, water-shrew, and brown rat ; bird remains included starling, redbreast, moorhen, coot, mallard, wood-pigeon and poultry chicks ; reptiles included slow-worm, grass snake and adder ; frog was the only amphibian ; there were also remains of the water-boatman bugs (Corixa and Notonecta) and the water-beetle Hydrophilus ; but a few remains of earwig, grasshopper, wood-lice, spiders and carabids or ground-beetles suggest that these were taken in the other prey consumed.

Birds on St. Kilda

St. Kilda was evacuated in 1931, and, except for the summer visits of a few of its former inhabitants, has run wild since that time. With the deliberate intention of founding a basis on which future comparisons might be based, T. H. Harrisson and David Lack made in 1931 a census of the birds on the island, and a new census by E. M. Nicholson and J. Fisher made in 1939 offers the first comment on changes induced by the absence of man (*British Birds*, 34, 29 ; 1940). The majority of the birds, land or sea, show no significant change, a specially noteworthy fact in the case of the gannet and fulmar petrel, considering the allegations that have been made regarding the destructiveness of man in relation to these birds. The black guillemot seems to be disappearing, only one individual having been seen in 1939, whereas six pairs were noted eight years before. On the other hand, shags and razorbills have increased, as has also the meadow-pipit. Striking additions to numbers were observed in the case of starlings, attributed to the supply of undisturbed nesting sites in the deserted houses and to the abundance of sheep ; of eider duck, attributed to the freedom from egg-robbing ; and of the common snipe, which curiously enough have colonized the enclosed dry fields about the village and were more frequent there than in the marshy haunts of the island, their normal habitat.

Indian Chalcid Wasps

Miscellaneous Bulletin 30 of the Imperial Council of Agricultural Research (India), by Hem Singh Pruthi and M. S. Mani, contains biological notes on Indian parasitic Chalcidoidea. It is in the main a host list referring to 175 species of these insects—the phytophagous forms of Chalcids, it may be added, are not included in this bulletin. Some fifty-six of the species dealt with are figured on the accompanying plates. From the list at the end of the bulletin it will be gathered that the Rhynchota feature as the most frequent hosts for these parasites, the Lepidoptera coming second in this respect. The insect collections in the Laboratory of the Imperial Entomologist contain a large amount of material, with data, concerning insect parasites. Information derived from this and other sources is being worked up and made available to workers in India and other countries. It is intended to publish the data so obtained, taking one group of parasites at a time. The series has been started with the present host-parasite account of the Indian Chalcids, concerning which no information has been available in comprehensive form at present.

Crinoids from the "Discovery" Expedition

D. Dilwyn John has beautiful material to describe, consisting entirely of Comatulids from the "Discovery" expedition (Crinoidea, *Discovery Rep.*, 18, 121–222; 1938). There are 326 specimens, mostly from depths between 100 and 600 m., 269 from the Antarctic region, the majority from the South American sector, a small number from the Ross Sea. 54 are from the Burdwood Bank and the Patagonian Shelf and are all of one species, *Isometra vivipara*, common to that region and to the Antarctic. The other 3, all *Comatula novæzealandiæ*, are from New Zealand. 9 species of the family Antedonidæ are new. A feature of the collection is the number of species which care for the brood and are viviparous. Most Comatulids shed their eggs directly into the sea and only 3 viviparous species were previously known, 8 more are now added, 6 belonging to new species and a new variety, and 2 which were not before recognized as being viviparous, making 11 viviparous Comatulids now recorded, 8 of which have only been obtained from the Antarctic. Out of 19 species known from the Antarctic 50 per cent are viviparous. A gradual series is shown in the methods of brood protection, from those with numerous eggs and larvæ with ciliated bands presumably emerging in the free-swimming stage to those with very few eggs which retain the young in the brood-pouch until the Pentacrinoid stage or, in one case, even as far as the young Comatulid. In all the viviparous species there is in the female a brood-pouch beside each ovary.

Maternal Constitution and Infant Mortality

An extensive analysis of the morphology of mothers and the mortality of their infants up to one year old has been made by H. C. Seibert (*Human Biol.*, 12, 232–246; 1940). Those mothers whose infant had died were significantly shorter in mean stature at exterior auditory canal, at suprasternal notch, and at lower costal margin and in mean sitting height, but not in mean trunk height. Body weight, span, head-length and -breadth, mean bia-chromal, bi-iliac hip and sagittal chest diameters were not significantly different in mothers with and without infant mortality. Several physiological phenomena were found to be uncorrelated with infant mortality.

Genetics of the Fowl

F. B. Hutt and W. F. Lamoreux (*J. Hered.*, 31 231–235; 1940) publish a map of the chromosomes of the fowl, involving six linkage groups and 21 mutant genes. With the exception of the sex chromosome, it is as yet unknown which of the 40 chromosomes bear these linkage groups.

Structural Changes in the Chromosomes of Drosophila

H. J. Muller (*J. Genetics*, 40, 1–66; 1940) has made an intensive analysis of the phenomenon giving rise to structural changes in the chromosomes of Drosophila. The genetically observed rearrangements are secondary effects to the primary changes brought about by irradiation. The frequency of these observed effects varies as the 3/2 power of the total dose for the range 1,000 r.–4,000 r. At lower doses the observed exponent rises nearly to the square, indicating that nearly all the rearrangements represent combinations of independent primary changes. There is little effect of temperature, wave-length or duration and intensity upon the frequency change brought about by irradiation. Therefore, change is caused by individual ion-effects which act separately. The 3/2 power relationship is accounted for by the survival value of the secondary changes and by the occurrence of unidentifiable multiple rearrangements. The author therefore brings forward strong evidence that 'breakage followed by union' as distinct from 'previous contact' is the phenomenon which gives rise to the observed chromosome rearrangements and other chromosome mosaics. Related work and theories are discussed.

Crystallization of Olivine-basalt

The Hat Creek basalt flow, north of Lassen Peak, California, has been described by C. A. Anderson (*Amer. J. Sci.*, 477–492; 1940). The lava was erupted along a line of north-south fissures, probably within the last two thousand years, and although it is holocrystalline for the most part, with an ophitic to sub-ophitic texture, it possesses many characters indicating marked fluidity at the time of eruption, for example, lava tubes, ropy pahoehoe surfaces, pressure ridges and slump scarps. It is shown that the Hat Creek basalt is of essentially the same composition and texture as the widespread Pliocene Warner basalt which covers a large area of north-eastern California, where it forms the major part of the Modoc lava plateau. The rock is rich in alumina and magnesia, and the history of crystallization is shown to be simultaneous separation of olivine and plagioclase, followed by pigeonitic pyroxene, plagioclase and iron ores. If chilling is rapid, hyalopilitic, intersertal or intergranular textures result from basaltic magmas of this composition, but with slower cooling, sub-ophitic textures develop with local areas of ophitic (poikilitic) texture. On the other hand, in plateau basalts of tholeiite type olivine is absent or rare and the lower amount of alumina results in a smaller proportion of felspar, so that the magma begins to crystallize near the boundary surface of the pyroxene and plagioclase fields and simultaneous crystallization of these minerals soon follows after the initiation of crystallization.

Upper Palæozoic Floras and Climates of South America

At the Eighth American Scientific Congress held in May 1940, several papers were presented dealing with the floras and climates of South America in Upper Palæozoic times. C. B. Read well summarizes present knowledge of the floras. The little that is known of the Devonian floras suggests identity with those of the northern hemisphere. Similarly, the Lower Carboniferous assemblages known from Peru and Bolivia show a very striking relationship to those of certain stages in the Mississippian of North America and the Lower Carboniferous of Europe, as well as to those of the Kuttung series of Australia and the Po series of India. The occurrence of Glossopteris floras and their relationships to tillites in the Falkland Islands, Argentina and Brazil is discussed. The general succession appears to be one in which the earliest floras are few in genera and species and completely austral. This is followed by larger associations in which distinct boreal elements appear. There appears to be a considerable body of evidence favouring a Carboniferous rather than a Permian age for these older Glossopteris floras and, in consequence, for the subjacent 'Gondwana' tillites.

M. de Oliveira Roxo discusses the habitat of the plant remains found in the coal-bearing deposits of South Brazil. He arrives at the conclusion that the plants flourished in a climate similar to that of the southern part of New Zealand at the present day, a climate that favoured the growth of a mixed flora with both cosmopolitan and 'Gondwana' types. In another paper the same author states that 17 species of 'Gondwana' plants, 8 of which are peculiar to Brazil, and 12 species of cosmopolitan plants have so far been identified.

A Seismograph for Microseisms

WITH the aid of a small research fund given by friends in St. Louis, U.S.A., it has been possible for the Department of Geophysics of St. Louis University to build a comparatively simple and relatively inexpensive seismograph especially for the study of microseisms. The instrument was designed by Rev. J. B. Macelwane, S.J., and built by W. F. Sprengnether (*Trans. Amer. Geophys. Union*, 1938). The design chosen was a small horizontal pendulum with tension-hinge supports, induction transducer, and electromagnetic damping. The relatively small dimensions and slight moving mass of only about two and one half pounds make the instrument readily portable. The boom of aluminium tubing carries a brass frame into which is set a brass box containing the two coils wound with a large number of turns of fine wire. This coil box is supported in the field of a strong horse-shoe magnet of Alnico alloy, and the wires are led back through the hollow boom to binding posts on the frame. At the outer end of the boom is a copper damping vane which moves in the fields of four opposing pairs of small commercial Alnico magnets, the separation of which may be adjusted to secure critical damping at any period desired. The current from the coils of the transducer is led to a Leeds and Northrup type *R* galvanometer of seven seconds period, the critical resistance of which is that of the coils in series. The period of the pendulum is adjusted to seven seconds, so that the whole system is in resonance with the microseisms that are to be studied. The results have been very gratifying, and excellent records are obtained with the magnification adjusted to about five thousand.

Reactions between Dry Salts

REACTIONS between the alkali halides in the solid state have been studied by H. L. Link and L. J. Wood (*J. Amer. Chem. Soc.*, 62, 766; 1940), mixtures of salt pairs being heated for long periods of time below the fusion point and the resulting mixtures analysed by the X-ray method. If the pair of salts containing the heavy cation united with the heavy anion and the light cation united with the light anion is called the stable pair, and the other mixture the reciprocal pair, then evidence for the partial or complete conversion of the reciprocal to the stable pair was obtained for forty out of forty-two reactions examined. Except in the mixtures containing lithium salts but no fluorides, no tendency for reversal of the stable to the reciprocal pairs was noticed. It was found in general that there was very little reaction in the solid state if the reaction temperature was more than 200° below the melting range, and that there was likely to be considerable reaction if the reaction temperature was within 100° of the melting range.

Organic Compounds of Tungsten

VARIOUS attempts have already been made to prepare organic compounds of tungsten, but with little success. The possibility of the existence of such compounds was, however, rendered very likely by the preparation of organic compounds of chromium, and later of molybdenum. Bearing in mind the types of chromium and molybdenum salts which were used in the successful preparation of their organic compounds, F. Hein and E. Nebe have now obtained similar compounds of tungsten (*Naturwiss.*, 28, 93 ; 1940). The best starting materials are non-electrolytic complexes of the type $[MeX_3A_3]$ and pseudo-salts of the type $[MeX_n]$. Tungsten hexaphenate, described by Funk (1936), was found to combine readily with phenyl magnesium bromide, forming a brown substance. This resembled in appearance the organic molybdenum compounds. Analogous compounds were obtained by the reaction of tungsten hexachloride and Grignard reagents or lithium phenyl. $(C_6H_5W)_2O_7H_4$ and $(C_6H_5)_3W_2O_8H_7$ have been isolated. In colour and reactions they resemble the corresponding molybdenum compounds. Like them, they are less stable than the organic chromium salts.

Apparent Places of Fundamental Stars

IT was recommended at the International Astronomical Union held in Paris in 1935 that the apparent places of stars in all astronomical ephemerides should be based on the mean places of the Third Fundamental Catalogue of the "Berliner Astronomisches Jahrbuch", known as FK3. It was further recommended that, from the date of the adoption of the star places of the FK3, the apparent places of the 1,535 stars in the FK3 and its supplement should be published annually in a single volume, under the auspices of the I.A.U. The first volume is now available (London : H.M. Stationery Office. 30*s*. net). Its preparation has been shared by the co-operation of the national almanac offices in Berlin, Paris, San Fernando, Washington and London. The computations of the apparent places of the stars have been shared by the first four, while Great Britain has been responsible for the collation and preparation of copy, independent checks and proof reading, and the British Government has borne the cost of printing. The 1,535 stars for which mean and apparent places are given consist of 853 10-day and 20 circumpolar Auwers' stars, and also 630 10-day and 32 circumpolar additional stars. In the reductions to apparent place, the constants of precession, nutation and aberration involved are those adopted by the Conférence Internationale des Étoiles Fondamentales, which met in Paris in 1896. The details relating to the numerical values and methods of reduction are given in each of the five almanacs issued by the countries participating in the work. The introduction is printed in English, French, German and Spanish, and full explanations are afforded of the various sections under mean places of stars, apparent places of stars, short-period terms of nutation, etc. There is an index to apparent places of stars which enables the page upon which the apparent place of any star is tabulated to be found from a knowledge of the star's name alone, and all names given to stars in the work are included in the index, which is, therefore, very complete. It is satisfactory to know that the recommendation of the I.A.U. regarding co-operation in the production of this volume has proved possible.

GRAIN DESTRUCTION BY INSECTS

BY DR. A. D. IMMS, F.R.S.

THE Department of Scientific and Industrial Research has recently published a report* dealing with the infestation of stored grain by insect pests. The survey which it describes was undertaken at the request of the grain trade and with its help and assistance towards the cost. The survey was carried out by the Department of Zoology and Applied Entomology of the Imperial College of Science under the direction of Prof. J. W. Munro. In order to maintain proper liaison with industrial concerns a Standing Conference was set up, under the chairmanship of Mr. W. McA. Gracie of the L.N.E.R. Co., to act as a consultative body. A Technical Consultative Panel, representative of many aspects of the problem, also established to make this knowledge available for the benefit of the investigation. Also, in order to assist the scientific workers engaged on the survey, a Grain Infestation Survey Committee was set up under the chairmanship of Sir Edwin Butler.

The field work of the survey has lasted about a year. Its most important result is the demonstration that infestation occurs throughout all the industries producing, housing, transporting, trading in, manufacturing, or using cereals and cereal products. No single industry, therefore, is in a position to accuse another as being the source of the prevailing evil. Compared with the elaborate series of processes used for the cleaning, conditioning and refining of flour, the prevailing methods of storage are almost crude.

The major problems appear to be the regulation of humidity and temperature. Until the causes of the rise in these two factors, as affecting stored grain, are better understood, effective regulation is not attainable. This aspect of the subject is a complex one and one which involves time for its solution. Meanwhile palliative measures for reducing and controlling infestation need to be considered. The survey has proved its value in recognizing and defining the main problems that need to be tackled. Good ventilation, general cleanliness, segregation of infested consignments and other simple methods of control have yielded results of value. Hygienic measures alone, however, will not provide sufficient control while heavily infested imported cereals and cereal products are brought into Great Britain.

The problem of insecticidal treatment comes to the fore; but there are real difficulties and disadvantages involved by their application. The importation of infested grain, as is continually going on, offers little encouragement to the dock authorities to provide modern hygienic transit vehicles and storage capacity. Also, unless these conditions are available it is unreasonable to expect the exporters to ensure freedom of their cargoes from infestation. In other industries the question whether the importing or exporting parties shall take first action has resulted in a stalemate except in one section of the dried-fruits industry. Timely measures by the Board concerned have resulted in a wholly negligible infestation of Australian dried fruits on the home market during the past five years. The way is thus pointed towards the reduction of one of the major evils of grain infestation.

The insects infesting grain are not natives of the British Isles: they cannot live and breed in our climate in the open, but only in barns, granaries, warehouses, mills, etc. The links in the chain of distributing infestation begin with the arrival of vessels from overseas and go from them to dock premises, vehicles and containers, and so to mills, merchants, breweries, maltings, farms, etc. The report has done good service in stressing the risks and formulating the problems that have to be met at a time when food conservation is of paramount importance. Also, as a beginning, the recognition of proper cleanliness and the separation of infested from clean grain are steps in the right direction. Since there is a whole chain of circumstances requiring control we have to bear the burden of neglect of applied biology at a time when the nation is facing its greatest crisis.

---

EARLY EXPLORERS OF SOUTHERN SOUTH AMERICA FROM THE UNITED STATES*

BY COLONEL LAWRENCE MARTIN,

DIVISION OF MAPS, LIBRARY OF CONGRESS

IN October 1829, Capt. Nathaniel Brown Palmer, who had discovered the mainland of Antarctica nine years earlier, sailed from New York in the brig *Annawan* and Capt. Benjamin Pendleton sailed from Stongington, Connecticut, in the brig *Seraph*. With them travelled five scientific investigators, Dr. James Eights of Albany, N.Y., Dr. John Frampton Watson of Philadelphia, Pa., Mr. Jerimiah N. Reynolds of Wilmington, Ohio, and two associates whose names are not known. These five were, as it seems, the first persons from the United States of America who carried out scientific investigations and inland explorations on the continent of South America. The captains of the two brigs independently explored the waters, largely uncharted, between South America and Antarctica.

---

* Abstract of a paper presented to Section VIII (History and Geography) of the Eighth American Scientific Congress.

Eights of Albany is the great name in the group. He was a physician and an accomplished naturalist, being well equipped in geology including glaciology, and highly competent in botany and zoology as well. The scientific investigations by Eights commenced in the south-east of the Argentine, where he landed at several places on the east coast of Patagonia in January 1830. He collected, *inter alia*, a crustacean, which he called *Brogniartia trilobitoides* and which is now known as *Serolis trilobitoides* (Eights), and also a plant afterwards identified as *Adesmia candida* by Hooker.

In the Isla de los Estados, or Staten Island, south-east of the Straits of Magellan, Eights continued scientific collecting. Here the botanical results included the plants *Viola Magellanica*, *Stellaria debilis*, *Galium Antarcticum*, *Senecio Eightsii*, *Clarionia Magellanica*, and *Pratia repens*. Doubtless some of these names have been modified in modern botanical practice.

In extreme southern Chile, upon islands near Cape Horn, Eights pursued his botanical and zoological studies shortly after January 22, 1830. A previously unidentified isopod, described as being found in unusual abundance in pools left by receding tides, was *Sphæroma bumastiformis*.

Eights' principal geological studies were carried out in the South Shetland Islands, an archipelago much nearer to Antarctica than to South America. Here he spent the month of February 1830. He was the first professional geologist to say "let [Antarctica] rocks their silence break". He showed that the South Shetlands were underlain by argillaceous conglomerate and sandstone, dipping south-east at angles of 12°–20°, intruded by basalt, and with carbonized wood in the conglomerate. Among recent plants, he found *Usnea fasciata*, *Aira Antarctica*, some species of Polytrichum and of Avena, one or two lichens, and a marine Fucus.

The sea life included two new species, *Glyptonotus Antarcticus*, and *Decolopoda Australis*, a 10-legged red sea spider, to say nothing of the more familiar fur seals, elephant seals, sea leopards, whales, porpoises, etc. Eights identified at least sixteen species of South Shetland birds besides five species of penguins. He worked out the regime of the South Shetland tides, finding only one ebb and flow every twenty-four hours in most localities, and studied the ocean bottom deposits.

The substantial geographical contribution of Captains Palmer and Pendleton in 1829–31, aside from taking the investigators to the places where they worked in the Argentine, the South Shetland Islands, and Chile, was their demonstration that no oceanic islands are to be found south-west of South America along the particular courses independently traversed by the two brigs. A logbook in the Library of Congress, that of the schooner *Penguin*, a consort of the *Annawan* during the voyage from Staten Island to the South Shetlands and on to the Island of Mocha in Chile, contributes to meteorology, oceanography, and ornithology by indicating (1) directions and forces of the wind day by day, (2) days when there was rain or sleet, (3) presence or absence of icebergs and other sea ice, and of floating kelp, (4) distribution of penguins and other oceanic birds. During the six weeks voyage of Capt. N. B. Palmer and his brother Alexander in the South Pacific, they sailed some 3,500 miles between February 20 and April 3, 1821, starting from Potter's Cove in the South Shetlands, continuing to a point in the ocean near lat. 58° 01′ S. and long. 103° 03′ W., and ending at the Island of Mocha south of Concepción, Chile. Watson and Reynolds sailed westward on the *Annawan* with Capt. Palmer.

Eights anticipated Charles Darwin by some nine years in observing glacial boulders carried in or left by floating icebergs and deducing from them the geology of unvisited lands poleward from the points of observation in the South Pacific Ocean and in the Shetland Islands. He probably sailed from this archipelago about March 1, 1830, in the *Seraph* with Pendleton and reached Chile early in May, after exploring south-westward and westward from the South Shetland archipelago in the waters between lat. 60° and lat. 70° S. and long. 54° and long. 101° W. By convincing deductions from two months of collecting meteorological, oceanographical, zoological, and botanical data, including facts about the prevailing winds, the fogs, snow, sea ice, icebergs with rocks in them, ocean currents, kelp, penguins, terns, and so on, he established the existence of a long stretch of unseen land. He thought it to be insular, that is an extensive chain of islands, but it was actually a portion of the antarctic mainland west of the Palmer Peninsula, a part of the *terra incognita* which Admiral Richard E. Byrd mapped by aeroplane flights from the *Bear* in 1940.

In Southern Chile, where the *Seraph* and the *Annawan* operated together during 1830–31, Eights presumably continued his geological, botanical, and zoological studies, chiefly in the lands adjacent to the Chonos Archipelago, the Gulfs of Ancud and Corovado, the Island of Chiloe, and adjacent islands and waters. Reynolds and Watson, landed by Pendleton and Palmer at the mouth of the River Arauco on July 23, 1830, spent four months or more in the interior of the so-called Araucania, exploring the lands, investigating the resources, and studying the native people. They brought back thirteen chests of scientific specimens which were placed in the Lyceum of Natural History at New York City, and two chests which were given to an institution at Philadelphia, Pa. Reynolds presented to the Boston Society of Natural History in Massachusetts a substantial collection of ornithological, botanical, marine, and mineralogical specimens, not only from the South Shetlands and Chile but also from Peru and the Galapagos Islands as well. Fragments of Eights' herbaria are in the State Herbarium at Albany, N.Y., other portions being with the collections of Sir Joseph Dalton Hooker in England. His geological and zoological specimens, and his field notebooks, have not been discovered.

These explorations and scientific studies in the southern parts of the Argentine and Chile, and in adjacent islands and waters, resulted indirectly from a message which John Quincy Adams, President of the United States of America, sent to the Senate and House of Representatives on December 6, 1825, only five years after the discovery of the antarctic mainland by Palmer. If Pendleton and Palmer had not taken Eights and Watson and Reynolds in 1829–31 to the localities alluded to above, there might never have been a United States Exploring Expedition of 1838–42 under Admiral Charles Wilkes. Eights' field-work in Patagonia and Isla de los Estados in the Argentine, and near Cape Horn in Chile, is one of the very early professional scientific investigations in the coastal regions of South America, as well as in the South Shetland Islands and South Pacific Ocean not far north of Antarctica, by a technically qualified scholar from North America.

TAXONOMY IN THE JUNGLE

BY PROF. JAMES RITCHIE

THE naming of species and their subordinate groups in laboratories and museums is a familiar process; indeed, it is the process by which the vast majority of animals have been named from the time of Linnæus onwards; and it has performed with reasonable success its two main objects, of labelling for convenience the population of the world, and at the same time of expressing degrees of natural relationship. But the demand for more precise methods of delimiting species is often made, and this demand takes two distinct trends, both influenced by the knowledge that species are not self-contained units but are composed of individuals the characters of which intergrade with those of related species. On one hand there is the plea for a statistical analysis of the morphological characters of populations before the risk is taken of dubbing a new species, as in Ginsburg's 'arithmetical definition' which expresses numerically intergradation or divergence. On the other hand there is a growing tendency to interpret characters in relation to environment, so that relatively small morphological differences which are constant throughout a habitat are regarded as of taxonomic significance.

There is no reason why the two methods should not be combined, each making its contribution to the validity of the final definition; but it must be recognized that for a vast part of the animal kingdom, as it is named, both methods would have been impracticable, the first because it demands large series of closely related forms, the second because it requires intimate knowledge of habits and restricted habitats. Had the *Challenger* collections awaited such refined tests, the systematic zoology of the ocean would have lost a foundation which on the whole has turned out to be solid and reliable.

On land the method of ecological taxonomy is more easy to apply than in the sea, unless it be on the shore and in the region between tides, and a close analysis of vegetation zones and of the peculiar characteristics of their inhabitants is bound to reveal unexpected affinities. A good example of this kind of analysis is Ivan T. Sanderson's account of "The Mammals of the North Cameroons Forest Area"[1]. It is true that the author minimizes the amount of study already done on these lines, for it is scarcely accurate to say that "within areas that may be defined as zoogeographical provinces little work has been done upon the distribution of animals" (p. 630) when one considers-- to mention a few—the investigations of Beebe, Hingston and others in the Amazon region, of Grinnell and Storer in California, the many American contributions to zonal distribution published particularly by the American Museum of Natural History (including one dealing with an area not far distant from Mr. Sanderson's chosen spot, Chapin's "Birds of the Belgian Congo", part I of which ran to 900 pages), and that even the knowledge of the animals of our own islands has been closely linked with habitats. But the author enters with the zest of a pioneer upon his inquiry, and has carried it out with such thoroughness that it will serve as a model for the zoologist in the tropical forest.

The place selected was the Mamfe Division, inland from Calabar, containing one of the largest remaining areas of unaltered primary rain forest in the whole of West Africa and including many contrasting ecological situations. The method of collecting was unusual: first a map-survey of the whole territory was made; then specimens collected in any ecological unit of the survey were examined and their appearance in the flesh recorded, with no attempt to name them by orthodox taxonomic standards. Indeed, instead of 'museum' characters, stress was naturally laid upon fresh colour variation, the distribution and shape of foot-pads, colour of iris, comparative measurements, and so on.

The general result was to reveal that "almost every variation, however slight, tallied with some recognizable alteration either of habitat or of conditions in the habitat" (p. 628), and that "most species were confined to a single vegetational zone . . . some extended over two such zones, but in only one case was an animal taken from more than a few paces beyond the edge of its zone or zones" (p. 631).

The minute analysis to which specimens were subjected brought out several interesting points bearing upon taxonomic characters. Colour, for example, was found to be unreliable, sometimes because it faded in different degrees according to the method of preserving the pelt—the skins of a maroon-coloured rat, *Malacomys longipes*, turned out grey, dark brown or bright reddish-brown, according to whether they were dried in a closed container, in shade or in bright sunlight. Some cases of local orange or red coloration appeared to be due to staining by a food plant, since the colour could be washed out. The dorsal bright green of four arboreal species is attributed either to the presence of minute algæ or to refraction (the unconvincing reason given for the latter suggestion being that the colour fades rapidly after death); but a minute examination of the hairs should have decided the matter once and for all.

Sometimes the field characters pointed to conclusions regarding classification which could not be deduced from museum skins, as when they indicated two or more divergent groups the evidence for which was lost in the preserved material, or when specimens "rather homogeneous in life" presented characters, in their preserved state, which might have warranted the creation of sub-species.

The author set out deliberately to test by his own thorough methods the validity of the criteria upon which systematics are based, and his conclusion encourages belief in the long-established technique, for when the field determinations were compared with recognized classification "the two sets of identifications coincided exactly as regards genera", and "in the majority of cases, also, species as defined in the field corresponded to species as recognized and recorded in current literature". In the matter of the finer subdivisions, however, difficulties presented themselves, and it was found to be difficult to equate the field subspecific types with the named subspecies.

Many interesting observations were made in the course of the exploration, such as that of the spherical hanging nests inhabited and said to have been built by *Cercopithecus preussi*, or of the giant and dwarf races of shrews here attributed to the abundance or scarcity of food available in different places, or of the cats (*Felis catus*) run wild in farmland and secondary forest which all had pale blue eyes, whereas in the village cats the iris varied between green and yellow.

Men of science, like Government Departments, are often pilloried for their misuse of the English language. Here there is a tendency to 'excessiveness'—"most forest animals tend to be excessively confined in their distribution"; two related species of Cercopithecus are "totally different"; "true constancy is exceptional". But the merit of this field monograph and of the author's drawings, coloured and uncoloured, of many species deserves the highest praise. If a word of advice may be given it is that a scientific paper, instead of indicating subtle colours in vague terms which convey different impressions to different people, would better describe them by reference to accepted colour standards such as those in Ridgway's well-known book on the subject.

ASPECTS OF THE TOTALITARIAN STATE

A SYMPOSIUM on the totalitarian State from the points of view of history, political science, economics and sociology has recently appeared (*Proc. Amer. Phil. Soc.*, 82, No. 1; 1940). Discussing totalitarian politics, F. M. Marx points out that totalitarianism and constitutionally safeguarded individual rights are incompatible. The corporative order is essentially an effort to interlock the entire occupational and social structure with the centrally controlled political hierarchy, and it cannot respect the difference between persuasion and brutal force. Totalitarianism is essentially anti-intellectual, but its character is dynamic and it would never have gained hold if it did not satisfy a human need not otherwise met. Its corporative features may well change the structure of the nation State so as to set a new international standard, and freedom of choice will only be retained by dealing effectively with those domestic conditions which cry out for redress.

Prof. Thomas Woody deals with the principles of totalitarian education, which he characterizes as aristocracy, anti-pluralism, anti-rationalism, collectivism and activism, the last-named differing from the liberal interpretation in permitting and encouraging only controlled activity, limited to the attainment of pre-determined goals. These principles constitute the basic educational framework of societies that look for stability and perpetuity on the basis of strict regimentation of the individual's capacities rather than through free development. They rest on the conviction that liberalism failed to show that men, if they had freedom, would use it for the common good.

Prof. H. Kohn, discussing the totalitarian philosophy of war, points out that in totalitarian philosophy war is the normal and welcome concomitant of all life, the supreme manifestation of vitality and virtue, an unalterable and dominating part of the whole system, whereas in the liberal conception wars exist only as a result of the shortcomings of the political and social order and may be overcome by the rational efforts of man. Ultimately, these two concepts of war rest on different concepts of the nature and destiny of man. Prof. C. R. Whittlesey, in reviewing the relation of totalitarianism to international trade and finance, suggests that the most significant feature of the economic policies of totalitarian States is their disregard of cost as the term is customarily understood, and from this fact arise most of the problems confronting countries competing with totalitarian States.

The totalitarian States, however, differ among themselves, as Mr. M. J. Bonn points out, as to the place of economics in the affairs of the world. In Italy and Germany, economics are only means which society needs for the pursuit of its main purpose, 'power', in order to dominate other societies and grow at their expense in accordance with the law of Nature which makes weaker and less numerous societies the prey of their stronger rivals. The pursuit of life, liberty and happiness for individuals as objectives of policy is senseless; they can only be reached as by-products of national welfare.

Communism, however, not only accepted but even stressed the rationalist doctrines of liberalism that growth and welfare of societies are regulated by immutable economic laws, the discovery of which enables man to develop a more or less perfect human society. It differs from its predecessors as to the proper nature of these laws, but they can be used to speed up development when they have been properly recognized. On the assumption that communists are in full possession of these laws, their dictatorial acts are not arbitrary. They merely impose the laws of the universe on those unable to discern them. Fascism and nazism are thus opposed to communism, because of its basis on reason and deduction and because it represents an impersonal scientific approach to objective truth by way of the intelligence and not through the emotions.

Discussing the novelty of totalitarianism in the history of Western civilization, Prof. C. J. H. Hayes considers that this novelty lies in the fact that dictatorial totalitarianism is really totalitarian, monopolizing all powers, subordinating all institutions and groupings, leaving no room for the free play of individual wills and recognizing no utility in free inquiry. Secondly, it commands and rests upon mass-support, and is not the affair of an aristocratic class or military caste. Thirdly, it is maintained, and its overthrow rendered unusually difficult, by novel and marvellously effective agencies of popular education and propaganda. It also possesses an allure through the emotional and essentially religious spirit which its leading apostles have infused into it. It has evolved a new pattern of methods and techniques, and in its exaltation of might and force as an end in itself is another novelty. It is essentially a revolt against the whole historic civilization of the West, but as an antidote to undue pessimism Prof. Hayes points to the improbability of a novelty of the last two decades outlasting what has long endured, and secondly to the resourcefulness of man, which has as often brought him liberty and fraternity as his inertia and submission have brought him dictatorship and slavery.

INDUSTRIAL INJURIES IN WAR-TIME

A REPORT by Prof. H. Levy on "War and Industrial Injuries" which has been issued by the Fabian Society (Tract Series No. 253) emphasizes the importance in the war effort of the fitness of the army of industrial workers behind the soldier, and directs attention to the cost of industrial accidents not only in sums paid for compensation but also in the loss of working time, both direct and indirect. In present circumstances it is emphasized that we must use to the full every ounce of man-power we possess that can be employed on production and that the present arrangements for preventing accidents and still more for the treatment of injuries and of industrial disease result in a very great and unnecessary waste of man-power—a wastage which is likely to be enormously increased under war conditions.

Prof. Levy therefore urges that one of the most important single contributions to the war effort would be the immediate introduction of expedients designed both to minimize the occurrence of accidents and to improve the facilities for treating the injuries resulting from them. The proposals put forward are essentially intended for the consideration of the Royal Commission on Workmen's Compensation, as any final solution involves drastic reform both of the law of workmen's compensation and the system of National Health Insurance. The main purpose, however, of any immediate proposals should be to create throughout the industry of this country institutions charged with the continuous and positive duty of preventing accidents so far as possible, and, where accidents occur, of providing for rapid and effective treatment of the victim. The changes now being made in factory administration, and the establishment under the chairmanship of Mr. Ernest Bevin of a new Factory and Welfare Advisory Board, provide a unique opportunity to use the new powers of the Ministry of Labour to extend and develop this type of organization over the whole of industry.

With regard to organization, the essential is that for a well-established industry of any size those who are vitally concerned in the running of the industry and who understand its problems should be entrusted with the task of preserving its man-power. Where joint standing committees do not exist, associations of employers and employees should be asked to form committees and compulsion brought to bear if this is not done voluntarily within a limited period of time. For small, scattered or ill-organized industries or occupations the Ministry should itself set up a welfare and safety organization partly of official members and partly of representatives of those engaged in the trade or occupation. To function effectively, such committees must be given really wide powers, including the right to visit any plant in the industry with which they are concerned, to inspect its safety provisions, make additional suggestions and under prescribed regulations inflict fines for the non-observance of safety provisions. The committees should be under an obligation to provide medical treatment for injured workers where the injury is serious, the treatment to be arranged so as not to interfere with existing arrangements, which at present are sketchy and inadequate. The committee would also be able to arrange far more efficiently than any centralized board for special attention to the particular problems of its own industry.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SUPERVISOR OF DOMESTIC SCIENCE TRAINING in Jamaica—The Secretary (I.P.R.), Board of Education, Kingsway, W.C.2 (August 26).

PROFESSOR OF GEOGRAPHY at the Higher Teachers' College, Baghdad—The Secretary (I.P.R.), Board of Education, Kingsway, W.C.2 (August 26).

TEACHER (MAN) OF ENGINEERING SUBJECTS in the South Dorset Technical College, Weymouth—The County Education Officer, County Education Office, Colliton House, Dorchester, Dorset (August 26).

PROFESSOR OF HOME SCIENCE in the University of Otago—The High Commissioner for New Zealand, 415 Strand, W.C.2 (August 31).

LECTURER IN BIOCHEMISTRY in University College, Dundee—The Secretary, The University, St. Andrews (August 31).

GRADE II (C) LECTURER IN THE DEPARTMENT OF MECHANICAL ENGINEERING—The Secretary, The University, Birmingham 3 (August 31).

FOOD POLICY AND EUROPEAN RECONSTRUCTION

IN the rude awakening which has come to public opinion in Great Britain and indeed elsewhere since the spring of this year, it is significant that the intensification of our national effort in the prosecution of the War has not eclipsed consideration of the problems which will confront us after the War in the task of reconstruction, whether in Great Britain or in the rest of Europe. In part it may be true that we are compelled to offer an alternative to the serf plan of European reorganization which Hitler offers. We cannot allow his plan to unite Europe to be propagated abroad without at least the broad outlines of a juster scheme which free men and nations could prepare.

The constructive and creative thought lying behind propaganda of this type is indeed a part of the war effort, to which it could well be argued that the Ministry of Information or the British Council might devote more attention and energy. The livelier and keener attention which is now being given to this question and the major problems it presents, as compared with the more academic debates of last autumn are not, however, primarily due to questions of propaganda or prestige. Fundamentally, they are due to the growing realization that the social and economic orders are changing and will demand a new type of society after the War if stability and security are to be achieved.

The mingling of the streams of social and international policy has thus forced us to consider reconstruction and the rebuilding of world order as part of the higher policy directing our war effort. It is indeed fortunate, as we have many times insisted, that much of the planning demanded primarily for war purposes frequently lends itself admirably to planning for reconstruction.

Prof. E. H. Carr remarks in "The Twenty Years Crisis" that ultimately the best hope of progress towards international conciliation seems to lie along the path of economic reconstruction. The same view that economic reconstruction to make it impossible for Europe again to be afflicted with economic distress like that of 1929–33 is a peace aim of the first importance has been repeatedly reiterated during the last twelve months. It is a main theme of Mr. J. E. Meade's admirable study "The Economic Basis of a Durable Peace" (London : George Allen and Unwin, Ltd., 1940. 6*s*. net.), in which he outlines a basis upon which a just and efficient system of international economic relations would be built.

A feature of the scheme is its endeavour to raise the general standard of living so far as possible and reduce inequality between nations and between classes. This would be done partly by the device recommended by the Bruce Committee and the editors of *Planning* of raising revenue to be spent in developing the more backward regions ; in enabling the Balkans, for example, to take full advantage of the technical knowledge, the experience and the superior credit of more prosperous States. The importance of this task to the rest of the world is well brought out by Mr. F. L. McDougall, the Australian representative on the Imperial Economic Committee, in a valuable pamphlet "Food and Welfare" (Geneva Studies, vol. 9, No. 5, November 1938. Geneva Research Centre). In that area of Eastern Europe the economy depends almost entirely on primary products and material civilization has been retarded by their unhappy history.

A European development fund administered in that area with no after-thoughts, with no purpose except that of the improvement, economic and political, of those populations, would help to solve poverty throughout Europe in raising the level of life among the poorest peoples. These peasant populations, it should be remembered, provide almost virgin markets for industrial products. While the local consumption of protective foods must be increased in these peasant districts if a satisfactory level of health is to be ensured, these areas could still meet a large part of the demand for increased supplies of dairy products, eggs, fruit and vegetables for industrial Europe which national nutrition policies would postulate.

If, therefore, the war exigencies lead us to envisage and pursue an adequate policy of nutrition as part of our food policy, the development of that policy of nutrition in the very forefront of our economic policy on the lines recommended by the Bruce Committee should follow as a matter of course after the War. The placing by the industrial nations of improved levels of nutrition and rising standards of living in the forefront of their economic policies would create large new demands for food and raw materials. Besides stimulating their own agricultural production, especially of liquid milk, vegetables and the other more perishable forms of the protective foods, this would necessitate large increased imports of energy foods, animal feeding stuffs and the less perishable protective elements. Thus imports would be paid for by increased exports to the predominantly agricultural countries, with the result of markedly increasing world trade.

The profound disturbance to food production and distribution in Europe caused by the German occupation of Denmark, Holland, France and other countries in no way invalidates this conclusion that all nations feel the benefit of advances in nutritional policy, and it is against this background and in this prospective that we must assess proposals at present being put forward regarding the relaxation of the blockade or the storage of foodstuffs against famine. The appeals to the well-known philanthropy of the American people to break the blockade clearly derive their inspiration from enemy sources. The legal and moral issues at stake have been admirably summarized by Prof. A. L. Goodhart, an American who is professor of jurisprudence at Oxford in a letter in *The Times* of August 8. The distress which is already being felt in the countries occupied by Germany is largely the result of the deliberate policy of the German Government which has exploited these territories by denuding them of everything that could be added to German reserves or serve the purposes of German industry. The recent assertions from Germany that her food situation is absolutely secure further invalidates the claim that Germany should be relieved of responsibility for the feeding of those she has conquered and plundered.

The situation in Europe to-day presents no parallel or analogy with that of occupied Belgium in the War of 1914–18 when supplies were sent into occupied Belgium for distribution to the civilian population under neutral control. To-day no neutral control could be devised which would afford the slightest guarantee against abuse of any philanthropic enterprise. Any supplies reaching Nazi-occupied Europe are a direct or indirect asset to Germany and would be used without scruple for her own purposes.

If, therefore, any relaxation of the blockade of any country under German domination is unthinkable, reaffirmation of the integrity of the blockade might well be accompanied by an assurance of immediate relief as soon as that domination is removed. It is the constant purpose of Great Britain and should be a first concern of the Ministry of Information to strengthen the spirit of independence in the occupied countries, to encourage their will to resist and engender a consciousness of comradeship with those outside who are carrying on the struggle.

These are among the reasons which give fresh pertinence to the planning of a definite policy for the relief of Europe as soon as the downfall of Nazism is achieved. Such a policy would involve the co-operation of the United States and of other overseas countries, including the British Empire, some of whom have already displayed a special interest in nutrition problems.

If the situation is to be met, planning on scientific lines is essential. Much indeed of the basic knowledge is already available through the inquiries set on foot by the Bruce Committee. In the building up of large stores of surplus foodstuffs ready to be shipped into Europe as soon as Nazi domination comes to an end, as suggested by Colonel Meinertzhagen, we must take account not only of surpluses accumulating in the Americas but in Africa also. As Dr. Julian Huxley points out in a recent issue of *The Times*, if may be necessary to buy up surplus products, not only of human foodstuffs but also of animal foodstuffs and other raw materials, if the entire economy of certain large tropical regions is not to collapse. Some surpluses, such as vegetable oils, require processing, involving in turn the purchase of suitable machinery from countries whose industry is not overtaxed by armaments production and this, like the provision of storage facilities, should form part of a comprehensive plan.

Dr. Huxley's proposals indeed merit close and immediate attention. To draw up such a programme now is not only an elementary measure of foresight. It would also demonstrate that democracy can plan for the needs of peace as decisively as a dictatorship, and without sacrificing the essentials of freedom. It is the most effective answer to the pretence that British policy is bringing starvation to Europe. It is not enough to point out that it is Nazi Germany which is starving Europe. Active preparation to feed Europe as soon as the present tyranny is overthrown is the first step to the establishment of a new European order enshrining the ideals for which Great Britain and those with her contend.

The supreme need behind such a plan is for enough public spirit and enlightenment to break through prejudices and inhibitions and act with courage and imagination. Alike in the prosecution of the struggle to which we are committed, and the building of a juster and more tolerable social order when victory has been achieved, there must be no weakness in the face of vested interests or conservative prejudice.

HENRY BESSEMER AND SIDNEY GILCHRIST THOMAS

Sidney Gilchrist Thomas
An Invention and its Consequences. By Lilian Gilchrist Thompson. Pp. 328+8 plates. (London: Faber and Faber, Ltd., 1940.) 12*s*. 6*d*. net.

IN 1856, an Englishman who had recently invented a rotating projectile was witnessing gun-trials with it on a French artillery practice ground near Paris. At that time, both gun and projectile were made of cast iron. These trials were a failure because of the frequency with which the gun burst, and the French commandant, who was in charge, said to him: "This invention of yours will require a better gun than one made of cast iron." So Henry Bessemer, for it was he, returned to England to make a gun tube that would not burst on firing.

He set to work at a foundry in St. Pancras, and after a few experiments conceived the idea of removing the impurities from molten cast iron without external heat, by blowing air through it and oxidizing them. He was a man of considerable financial resources, and in less than a month had carried out his experiments successfully. He constructed a 'converter', which was simply a pear-shaped iron shell with a fireclay refractory lining fitted with tuyeres through which the air was blown. The only difficulty he had in conducting the first experiment was with his assistant, who thought he was quite mad. However, he succeeded in making him pour the melted iron from the cupola into the converter and started to blow air through it. Neither of them knew what would happen and at first nothing did happen; the reaction started quietly but then became very violent, and nearly set the place on fire. When it had finished, the converter was rotated downwards and the liquid metal poured out into a mould. In this way, he obtained an ingot of what he regarded as malleable iron. Malleable it certainly was, as numerous experiments showed. The product is what is to-day called 'mild' or 'soft' steel. He had within half an hour raised the temperature of a mass of fluid pig iron several hundred degrees, removing the greater part of the impurities without the use of any fuel, and produced a steel which was not brittle. This experiment inaugurated the era of cheap and plentiful steel.

But, to use a modern expression, Bessemer had 'got away with it' rather too easily. Quite by chance, he had used one of the few suitable brands of low-phosphorus pig iron made in Great Britain, and that is why his first experiment was successful. At that time, there was no such thing as the chemical control of the composition of cast iron. Various iron-makers set to work to repeat this process, using their own brands of cast iron, not knowing that what was right for the refinery or puddling-furnace was wrong for converters lined with siliceous materials. Almost without exception the irons produced were worthless since they were quite brittle. This brought about a complete reaction against the process which was denounced as the dream of a wild enthusiast, such as no sensible man could for a moment have entertained.

In those days there was no Iron and Steel Institute, and Bessemer had to try to solve his difficulties himself. He established the fact that it was the phosphorus in the cast iron, which was not removed in the 'blow', which made the resulting steel brittle, and he then tried to remove it by various methods, but without success. By using Swedish non-phosphoric pig iron, however, he was always able to convert this into malleable steel. By now, however, the process was discredited and nobody would take it up, so that he was forced to become a steel-maker himself. He went into partnership with four other men and established a works in Sheffield. This partnership lasted fourteen years. The process was so much cheaper than the established methods of steel-making that their profits were very large. During this period they made eighty-one times their capital. Bessemer thus solved the problem of making steel without fuel from low-phosphorus pig iron. But his process was of limited applicability since the majority of ores distributed over the earth's surface contain too much phosphorus to be amenable to it.

Some fifteen years later, an evening-student at the Birkbeck Institute, listening to a lecture on cast iron, heard the sentence, "The man who eliminates phosphorus by means of the Bessemer converter will make his fortune". The student was at that time a junior clerk in the Thames Police Court at a salary of £90 a year, and his name was Sidney Gilchrist Thomas. That remark lit the flame of desire in his mind to solve the problem. He began experiments in his humble quarters, and enlisted the help of his cousin, Percy Carlyle Gilchrist, who was the chemist at an iron works at Cwmavon in South Wales. Both of them had to work with very slender resources in their spare time. Naturally, progress was slow and the results were frequently disappointing; but they persevered and in the end took out two patents. But by this time they had exhausted almost all their financial resources. However, Mr. Martin, the general manager of the Blaenavon Steel Company in South Wales, came to their assistance. Further experiments were made and, finally, a third patent was taken out in 1878. In the meantime, the Iron and Steel Institute had been founded (1869). Accordingly, Thomas and Gilchrist prepared a paper for presentation at its autumn meeting in Paris in that year. The paper was entitled "On the Elimination of Phosphorus in the Bessemer Converter". So little was its importance realized that it was not even read, but was adjourned until the spring meeting of 1879. In the interval, the inventors got into touch with Mr. Windsor Richards, of Bolckow, Vaughan and Co. The personality of Thomas, in particular, greatly impressed him. Accordingly, arrangements were made for a phosphoric charge to be blown at the works in question, and this was successfully done in April 1879. Thomas and Gilchrist had established that three essential conditions must be satisfied if the phosphorus was to be eliminated from the cast iron.

(1) It was necessary to line the converter with basic material, not merely of the correct composition but also of the requisite temperature stability, so that its adhesion to the converter walls during the blow was maintained. Such a lining could be manufactured from burnt dolomite.

(2) It was essential to form a rich basic slag at an early stage of the process.

(3) While carbon, silicon and manganese were removed at an early stage of the 'blow', the phosphorus was not diminished until later. This necessitated the so-called 'after blow' during which about 80 per cent of the phosphorus is eliminated.

This experiment was completely successful and accordingly, when Thomas and Gilchrist read their paper at the May meeting of the Institute in 1879, they were in a strong position. At this meeting, Sir Henry Bessemer was present and congratulated them on having solved the problem which had proved too much for him. It was admitted by the great majority of critics that they had established their case.

Thomas possessed a very acute mind, and his experience on legal matters at the Thames Police Court stood him in good case when it came to the filing of the patents for what is now known as the 'Basic Bessemer Process'. From being a poor man, he quickly became a well-to-do one. He and Gilchrist thus completed the original discovery of Bessemer by rendering it available for iron ores which contain sufficient phosphorus. In addition, in their process the slag produced is a valuable agricultural fertilizer, and may be regarded as an equally important product.

Although the above facts have been known for the last sixty years, the personal side of Thomas's life and work has only recently been disclosed. He, himself, died in 1885 when he was only thirty-five. His sister, Lilian Gilchrist Thompson, has published his life, under the title of "The Story of an Invention and its Consequences". She is in her eighty-first year. He left the money which he had made to her in a trust for charitable and social purposes. In writing this book, she has frequently let Thomas speak for himself, whether in the form of letters to his mother and herself, to whom he was devoted, or in a series of articles under the heading, "Technical Travel Talk", which he contributed to the columns of *Iron*. There are many who will be grateful to Mrs. Thompson for the story thus told. She has performed her task admirably. Thomas was a man who lived strenuously, and literally wore himself out. His is one of the great names in metallurgy, and he is one of the great benefactors of the human race.

H. C. H. CARPENTER.

CONTRIBUTIONS TO THE HISTORY OF SCIENCE

Osiris, Vol. 7
Edited by Dr. George Sarton. Pp. 616. (Bruges: St. Catherine's Press, 1939.) n.p.

TO those whose interest in science is wide enough to embrace the history of its development in all stages a volume of "Osiris" offers much attractive reading. The field covered is so extensive that few are likely to read all the articles with equal avidity. The contributors equally have shown complete diversity in their choice of subject and in the scale and manner of treatment. Thus the contents present a variety from which readers can make a choice according to their taste.

Each volume of "Osiris" is dedicated to some distinguished scholar. In this, the seventh of the series, tribute is paid to Prof. Gino Loria. His portrait, a biographical sketch by Prof. R. C. Archibald and a bibliography of his writings make a fitting opening of the volume.

A paper in German by Prof. J. Ruska follows, in which he attacks the problems set by the works of the Arabian alchemist Razi, the author of "The Secret of Secrets". These have had a curious fate, for while at least one MS. has passed unrecognized under another part of Razi's very elaborate full name, others which purport to be Latin versions have been mangled in the course of transmission and some have been attributed to Razi without any justification. To distinguish the true text is thus an arduous task, but this work of scholarship on which Prof. Ruska has embarked is essential for the history of alchemy.

The sexagesimal system retains its interest owing to the form of division still adopted for the hour and the degree. The origin of this system is attributed by M. F. Thureau-Dangin to the Sumerians; but his very interesting paper, which is translated into English, deals also with the wider subject of Babylonian mathematics. As this includes the solution of a quadratic equation by rules which represent the usual formula its historical importance is great. Whether this achievement is properly regarded as a beginning of algebra seems doubtful. It is a long way from Diophantus who used symbols, whereas the Babylonians certainly did not. Hence they deserve credit for remarkable skill in arithmetic, which is doubtless the parent of algebra, but the critical step from one to the other is surely to be found at some later date when algebraic symbols are explicitly introduced for the first time.

The development of geometry in the last century with the fundamental change of outlook involved is discussed by Prof. E. Nagel in a technical but very readable paper. He has traced the progressive advance towards more complete abstraction by which geometry has become more and more independent of physical content. Had it ceased to be "useful" in the process there would have been no need to agree with Santayana that it had become "a wasteful and foolish exercise for the mind" except in the same sense as the fugues of Bach. But of course geometry has not become less relevant to an understanding of the physical world through breathing a purer and wider atmosphere, and Prof. Nagel has not failed to consider the modified relation between the two spheres of geometry and observation.

The editor's charming study of Borodin goes far to justify a medium in which men of science can be treated as human beings. In his union of science and art Borodin was unique. As a professor of chemistry he gained his livelihood, played his part in the teaching of his generation and made a quite respectable contribution to the progress of chemical research. As a musician he was a composer of distinct originality and as such he will be longest remembered: *ars longa, scientia brevis.* A reference to William Herschel may be corrected on one point. It is true that Herschel did not run his art and his science in double harness all through his life. But it is not true that he was not a composer. Those who were privileged to hear a selection from his work played under the direction of Dr. G. Dyson at the Royal Astronomical Society conversazione a year or two ago learnt that Herschel's compositions are charming examples in the lighter eighteenth century idiom. In spite of their merit they remain unpublished in the possession of the family.

The paper by S. Gandz on the "Dawn of Literature" fills nearly half the volume and so is out of scale with the rest. That the author's industry in collecting material has been great is attested by some 750 references. But the whole has not been reduced to the form of a connected thesis, and it may be that the subject of oral tradition in the ages before writing was possible and afterwards is too wide for satisfactory treatment. It has many interesting aspects, alike in the religious and the secular, the literary and the scientific spheres. Here these aspects are neither exhausted nor brought into one clear focus.

Nothing need be said about the next paper by M. J. Pelseneer giving unpublished letters of Newton, because this has already been the subject of a note in NATURE. It is followed by one in which Dr. E. C. Watson describes the prominent members of the Paris Academy of Sciences in its early days. This article is based on engravings by Sébastien Le Clerc, a number of which are reproduced. In 1670, Le Clerc was engaged by Colbert as Court engraver and in this capacity he contributed illustrations to several notable works produced by the Academy with the direct encouragement of the king. To this circumstance is due a pictorial representation of the membership and apparatus of the Academy in several settings. This pleasant account makes it a matter for regret that no contemporary artist gave similar attention to the Royal Society.

The volume closes with a short article by Sister M. E. Keenan on "St. Augustine and Biological Science". Perhaps natural history would be more appropriate, and indeed the subject is rather literary than scientific. The source of Augustine's allusions is clearly Virgil and Pliny rather than Nature, and though he may have treated current lore with some reserve, his powers of observation do not seem to have been more than moderate.

H. C. Plummer.

SCIENCE IN BREWING

Brewing

Science and Practice. By H. Lloyd Hind. Vol. 2: Brewing Processes. Pp. xiv + 507–1020 + 62 plates. (London: Chapman and Hall, Ltd., 1940.) 56*s*. net.

It may be said, at some risk of repetition, that brewing is an art, developed throughout the centuries without aid from science. Science now steps in to explain what happens in the brewery, why certain procedures give good and others bad results. Research, both fundamental and technical, is increasing every year the value of science, now harnessed to the art of the brewer.

An example of this function of science in the brewery may be cited. The importance of aeration in securing a satisfactory brewery fermentation has been realized since Pasteur's time. In more recent times the purely mechanical function of aeration, that of 'rousing' or mixing the yeast back into the fermenting wort until it has finished the fermentation, has been stressed. Also within recent years the relationships between alcoholic fermentation, respiration and yeast growth have become much clearer. It now emerges that, fundamentally, aeration in the brewery fermentation vessel is merely necessary to secure healthy growth of the yeast from the small amount that the brewer seeds to the wort to the much larger amount that he normally removes from it. There is no scientific reason why a much higher yeast seed-rate should not be used in practice. This would result in a swifter fermentation and little time for multiplication. Aeration would be quite unnecessary in such a case. The fact is that beer is not, and never was, made in this way, and probably it would have a yeasty flavour and other different characters if it were so made. Moreover, the problem of a supply of healthy seed yeast would arise. But the apparent contradiction between theory (as propounded by Pasteur) and practice in breweries is explained. Science explains the brewers' empiricisms.

Such is one function of the excellent work under notice. To the technician in the brewing industry, it is of course, much more than a mere explanation of long-established practice. It is with its companion volumes a complete handbook of the brewer's art and craft.

The materials used in brewing had been exhaustively treated in vol. 1, which appeared about two years ago. The present volume deals with plant and processes, except that the whole of the processes involved in the bottling of beer are postponed for treatment in a third volume to appear later.

The chapters dealing with mashing are very good. Here, as elsewhere, the opportunity has been taken to incorporate into this volume recent scientific advances which have been published since the previous volume was written. There is also shown throughout a satisfactory blend of scientific discussion and practical empiricism. The processes of boiling with hops, cooling (involving flocculation of protein-tannin compounds), fermentation, conditioning of draught beer, and sections on relevant micro-organisms follow. An admirable chapter on bacteriology as it affects the brewer is contributed by Dr. J. L. Shimwell.

A large number of excellently reproduced photographs of brewery plant adorn the volume, whilst the photomicrographs of yeast in ultra-violet light are the best the reviewer has ever seen. A summary and list of references appear at the end of each chapter, whilst author and subject indexes terminate the volume. The author's long experience as brewer and chemist, supplemented by extensive reading and painstaking labour, have resulted in a book which should be of inestimable value to technicians engaged in the trade.

STUDIES IN FOSSIL BOTANY

An Introduction to the Study of Fossil Plants
By Prof. John Walton. Pp. x + 188. (London: Adam and Charles Black, Ltd., 1940.) 15*s*. net.

THIS book, intended for those who have had at least a year's university or college course in botany, will be welcomed not only by university students but also by those select readers who desire a brief, well-balanced account of the fascinating succession of floras that have clothed the earth. The value of the descriptive matter, which is clear and concise, is enhanced by the illustrations, which are generous in number and well chosen. The probable relationships between the living and the fossil representatives of the various groups of plants are adequately indicated, while fruitless speculation on the more problematical affinities has been avoided. D. H. Scott's "Studies in Fossil Botany" being now out of print, the book under review replaces it in the publisher's lists.

In his preface, the author expresses the hope that his readers will make a point of examining the actual specimens of fossil plants which are preserved in university and museum collections, and that they will institute active searches for fossils in such likely places as quarries and the spoil-heaps of collieries: such a course will indeed amply repay, in increasing understanding and zest, the trouble involved. Even the novice may hope to have the good fortune to find specimens which are worthy to be added to the priceless collections in our museums, and may also find hitherto unknown localities for fossils which may possibly yield a rich harvest of new forms.

The first chapter of the book classifies plant remains in general into compressions, incrustations, casts and petrifactions, and gives an excellent account of the many methods employed in investigating the specimens in the laboratory. Great advances have been made in a number of these methods in recent years, and Prof. Walton has been in the forefront of those who have made them; one of the most remarkable results of micro-palæobotanical research was his discovery of the oldest known (Carboniferous) liverworts (p. 22).

The body of the work deals with the chief groups of plants in the order of increasing complexity, each group being illustrated by a number of types. In the account of the Thallophyta it is shown that the recognition of fossil bacteria depends less on their external form than on the traces of their physiological activity. This would have been an appropriate place for a brief reference to the role of anaerobic bacteria in coal-formation and for mention of the recent work of Lipman, Farrell and Turner on the bacteria occurring in coal. On the other hand, the description of Pachytheca might well have been omitted, since its vegetable nature is open to doubt. The description of the early vascular plants is a particularly good review of exceptionally difficult material.

A reference to the spores which occur abundantly in most coal-seams is made in the account of the Lycopodiales, plants which disseminated spores in countless numbers. The preparation of graphs summarizing the vertical distribution of arbitrarily chosen spore-types in coal-seams has recently been pressed into service in the difficult task of endeavouring to correlate the seams. This method is, however, still in its early stages. While it may be doubted whether sufficient evidence has yet been adduced to warrant the statement (p. 57) that "a similar graph is usually obtained if the same seam is analysed in a different part of the coal-field", it is certainly not necessarily true that "a different seam will show quite a distinct form of graph".

The final chapter of the book, on the succession of the floras and climates, is full of interesting matter. The climate of Europe and North America during Upper Carboniferous times is described as "probably warm" (p. 135) and as "between temperate and tropical" (p. 174), but the plant evidence on this point may be regarded as less conclusive than even these statements imply. Furthermore, studies on certain other forms of contemporary life and on certain sediments have led to conclusions which are actually contradictory. Despite the uncertainty, as Prof. Walton points out, we have considerable evidence, important to the botanist, as to the ecological conditions under which the plants lived.

The text is completed by a representative bibliography and a useful index; the outline classifications given at the beginning of most of the chapters, and the several tables included in the text, are valuable guides to the complex botanical and geological divisions. This book is a stimulating account of the subject and admirably fulfils its purpose. Both the author and the publishers are to be congratulated on the production.

R. CROOKALL.

A Flora of Cambridgeshire

With an Appendix on the Origin and Drainage of the Fens. By Dr. A. H. Evans. Pp. xi+228. (London and Edinburgh: Gurney and Jackson, 1939.) 7*s.* 6*d.* net.

As there has been no Flora of Cambridgeshire published since Babington's in 1860, a modern flora of the county was much to be desired. Unfortunately this book does not fill the gap adequately, and compares very unfavourably with such a book as the recently published "Flora of Devon". For most species no dates or authorities are given for the records. For example, twenty localities are given for *Astragalus glycyphyllos*, of which fifteen occur in Babington's Flora; the other five are new, but no indication is given of their date or of where the plant still occurs. Relhan's name is cited for the Shelford locality but not for Madingley or Impington, from which places no more recent record than his was known to Babington.

Unfortunately, also, the book contains many errors. *Prunus insititia* is not a green-twigged woodland plant nor is *Juncus bulbosus* "not uncommon" but very local. The Cambridge University Herbarium has not been properly consulted, so that many important records are entirely omitted. As examples may be cited *Medicago denticulata* (a plant not included in the Flora) from near March (Little), *Cardamine hirsuta* from Chatteris and *Apium inundatum* from Ditton and Hardwick.

While it is useful to have a record of the author's great personal experience of the plants of the county and while the book contains much useful information, the need for a good modern Flora of Cambridgeshire remains unfilled. E. F. Warburg.

Essai de météoropathologie

Physique, clinique, thérapeutique. Par W. Kopaczewski. Pp. 296. (Paris: J.-B. Baillière et fils, 1939.)

That certain disorders are caused or influenced by environment, atmospheric conditions, weather, has been surmised from ancient times—for example, ague and swamps, rheumatism and dampness—and in his introduction to this book the author reviews the contradictory evidence thereof. It is also often difficult to disentangle purely environmental from other factors; thus, we now know that swamps generate ague only because they breed the mosquitoes which convey the disease. The author first surveys the physical factors of the air and sun concerned with climate, the physiological details connected with these, and meteorological data. Next, regulation of body function necessary in a changing environment is dealt with, followed by a discussion of the results upon the body of extreme variations in atmospheric pressure and temperature, exposure to actinic rays, and electric shock. Finally, the treatment of the 'shock' thus caused is considered.

Unfortunately, no information or discussion is included respecting the more subtle influence of minor meteorological disturbances upon body function, such as ordinary variations in barometric pressure, in humidity and in temperature, alterations in direction and force of the wind, and the like, and it is about these that we are still so ignorant. A valuable section of the book deals with the climate of France, with full meteorological data, and illustrated with fourteen excellent charts.

Aspects of the Calculus of Variations

Notes by J. W. Green, after Lectures by Hans Lewy. Pp. vi+96. (Berkeley, Calif.: University of California Press; London: Cambridge University Press, 1939.) 4*s.* 6*d.* net.

This little book contains valuable notes taken of lectures delivered at the University of California in the spring of 1938. The aim of the lecturer was to acquaint the student with a skeleton of the methods, rather than the theorems, of the calculus of variations. Familiarity with the chief methods used in the study of functions of a real variable is assumed.

The notes are divided into six chapters which deal with the derivation of the necessary equations for a continuous function to assume maximum or minimum values; quadratic problems in one variable; the Weierstrassian field theory; a general theorem on existence of absolute minima; an introduction to harmonic functions and the Dirichlet problem; Plateau's problem and conformal mapping. As the literature on these aspects is either of recent date or is not easily accessible, these interesting notes should be of much use to all students of this subject.

New First Course in the Theory of Equations

By Dr. Leonard Eugene Dickson. Pp. ix+185. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1939.) 10*s.* 6*d.* net.

This book is founded upon the author's earlier work but is written "in a more expansive style with many illustrations either following or preceding the introduction of new ideas or topics, and with minute attention to details". Proofs have been simplified, so far as possible; more exercises have been added, whilst others have been discarded and additions have been made to the text in order to bring it up to date.

Introductory chapters deal with complex numbers and the elementary theory of roots, after which cubics, quartics and the use of graphs are discussed. Then follow the various methods in use for solving numerical equations, brief discussions of determinants, matrices, symmetric functions, elimination, resultants and discriminants. Finally, the general theory of polygonal constructions is considered analytically. This is a logical sequel to an earlier chapter on some particular impossible constructions by ruler and compasses. The book closes with an appendix on the fundamental theorems of symmetric functions and of algebra.

As the subject naturally touches the borders of so many other fields of study, it is always difficult to render a treatment of the theory of equations in any way complete. Nevertheless, the author has produced an interesting first course which should be quite useful to students as an introduction to the subject.

THE SUPPLY OF ANIMAL FEEDING-STUFFS

By Dr. Norman C. Wright,

Director, The Hannah Dairy Research Institute, Kirkhill, Ayr

THE statement made recently by the Minister of Agriculture that British farmers should aim at self-sufficiency in regard to their supplies of animal feeding-stuffs raises the interesting question as to whether such self-sufficiency could, in fact, actually be achieved on a nation-wide scale.

Some two years ago I made an estimate of the total supplies of home-produced and imported feeding-stuffs available for the live-stock population of the United Kingdom[1]. A recent re-examination of the feeding-stuffs position[2] has confirmed this earlier estimate. Briefly, it may be stated that the total pre-War supplies amounted to about 42 million tons of feeding-stuffs (expressed as dry food), which provided some 22 million tons of starch equivalent and 3½ million tons of protein equivalent. Roughly 60 per cent of these nutrients were derived from British grassland, either in the form of grazing or hay, about 14 per cent were supplied by the home production of cereals and root crops, while various by-products (such as brewer's and distiller's grains and fish and meat meals) provided a further 1 per cent. The remaining 25 per cent had to be imported from overseas, either in the form of cereals (chiefly maize and wheat offals) or oilseed products. The volume of imported feeding-stuffs which the British farmer is urged to replace by home-grown produce may, therefore, be roughly estimated at 10 million tons, containing about 5 million tons of starch equivalent and 1 million tons of protein equivalent.

In considering how far this feeding-stuffs gap can be closed, three salient facts must be taken into account. First, of the total home-produced nutrients, about two-thirds are obtained directly from summer grazing. Any curtailment in the volume of imported feeding-stuffs will therefore result in a relatively larger gap in the winter supplies, and any increase in home production will, in consequence, need to take the form of feeding-stuffs which are capable of conservation for winter use.

Secondly, there are two classes of stock, pigs and poultry, which cannot utilize large quantities of coarse feeding-stuffs, and which have therefore to subsist chiefly on cereals and protein-rich concentrates. Such stock are liable to be particularly badly hit by any reduction in the feeding-stuffs imports.

Thirdly, it must also be realized that a reduction in overseas imports may not be the sole cause of a shortage of feeding-stuffs. Disorganization of the home fishing industry has, for example, already caused a reduction of about 60,000 tons in the supplies of fish meal, while the threatened raising of the extraction rate of wheat to 85 per cent would reduce the quantity of offals available for live-stock by as much as 900,000 tons. Again, the ploughing-up campaign, while adding materially to the total food production of the country, will itself cause a reduction of between 50,000 and 100,000 tons in the supplies of protein and starch equivalent which will be available for animal feeding.

The above facts will inevitably increase the difficulty of closing the feeding-stuffs gap. In attempting to close this gap, three lines of action are possible: first, the exploitation of new sources of supply; second, the adoption of modified feeding methods; and third, a compulsory reduction in the live-stock population.

As regards new sources of supply, a wide variety of methods has been suggested for increasing the home production of nutrients suitable for stock feeding. A recent review of these methods[3] indicates, however, that few of them are capable of making a really significant contribution towards closing the feeding-stuffs gap. For example, the more efficient utilization of kitchen waste, which was the subject of a special article in Nature[4], could at best only replace about half of one per cent of the pre-War imports, while improvements in the methods of conservation of slaughter-house offals might achieve an increase of about the same order. The pre-digestion of straw with alkali, the potentialities of which were explored by Germany in the War of 1914–18, is at present the subject of intensive research in Great Britain. The object of the treatment is so to improve the nutritive value of straw now used for litter that it can usefully be fed to live-stock. The treatment of, say, 10 per cent of such straw (an optimistic estimate in introducing a very novel practice to a very conservative industry) would, however, only replace 2 per cent of the energy content of the pre-War imported feeding-stuffs, while it would have no effect on the supply of protein.

So far as the protein portion of feeding-stuffs are concerned, the use of synthetic non-protein nitrogen compounds such as urea has been advocated as a substitute for part of the protein in the rations of ruminants. In order to make good the low protein content of cereals *in the rations of dairy cattle alone* it would, however, be necessary to envisage an output of urea of the order of 50 tons per day, a quantity which is certainly well beyond the present capacity of the country's production plant. Again, it has been suggested that, as an alternative means of making good the protein deficiency of home-produced feeding-stuffs, the cultivation of protein-rich crops such as beans should be increased. This could, of course, only be done at the expense of an existing crop, say oats. If this latter fact is taken into account, even the doubling of the present bean acreage would only increase the supply of protein equivalent by about 10,000 tons (1 per cent of the pre-War imports), while it would simultaneously *decrease* the supplies of starch equivalent by about 16,000 tons. The same general finding applies to all other crops which have been advocated as potential sources of increased supply.

It is clear from the above facts that most of the suggested new sources of supply, while no doubt of use on certain individual farms, cannot be expected to contribute significantly towards the closing of the feeding-stuffs gap. There remains one further source of supply which has not been discussed, namely, grass silage. The Ministry of Agriculture is clearly pinning much faith on the development of this form of conserved fodder as a means of replacing imported feeding-stuffs. The immediate aim is stated to be the production of one million tons of silage from the present season's aftermath. This would, it is true, only replace about 2–3 per cent of the pre-War feeding-stuffs imports. The above figure is, however, clearly an interim one: a far greater effort would obviously be called for over a complete grazing season. In this connexion it may be noted that a ten-fold increase in the present objective, that is, an annual production of ten million tons of silage, would replace about a quarter of the pre-War imports—a really substantial contribution. Although such a large output might appear somewhat impracticable, it would require the provision of only three small (30–40 ton) silos on every agricultural holding of more than 150 acres—an achievement which should not prove impossible in time of really serious emergency.

It would not perhaps be out of place to mention at this point one other *indirect* method of increasing the proportion of home-produced nutrients, namely, a return to summer milk production and an intensification of summer meat production. The term 'indirect' is used because the method involves the storage of the finished products themselves (dried or condensed milk, cheese, meat, etc.), instead of the storage of the grass herbage as hay or silage. The method would entail a drastic changeover in management (for example, in rearranging calving dates), but as a long-term measure has obvious advantages.

Taking into account all the above sources of supply, it does not appear that they could replace more than about one third of the pre-War imports of feeding-stuffs. For further savings it is necessary to turn to the second line of action, namely, the adoption on the farm of more economical systems of feeding.

There is no doubt that substantial savings could be effected by this means if rationing on a basis of modern feeding standards were to be adopted on a nation-wide scale. The general tendency of recent animal-feeding experiments, whether with cattle, sheep, pigs or poultry, has been to show that the older feeding standards can be markedly reduced without adversely affecting the health or productivity of the stock. Reductions of the order of 20 per cent may, indeed, be made in the protein and/or energy contents of most rations. Again, the methods of feeding beef cattle and sheep could well be modified under war conditions, when the provision of an *adequate quantity* of meat is more important than the attainment of *superfine quality*. Again, war-time methods of stock-feeding (for example the Lehmann system of pig-feeding) permit the use of more coarse feeding-stuffs (and therefore of more home-produced roughages) than is normally considered practicable.

It is not easy to estimate the total savings in imported feeding-stuffs which might be effected by the widespread adoption of these various measures. A recent review[3] indicates that such savings would probably amount to nearly a quarter of a million tons of protein equivalent and to more than a million tons of starch equivalent, that is, to more than a fifth of the estimated total feeding-stuffs gap.

New sources of supply and the more economical use of existing supplies together might, therefore, make good about half the pre-War imports of feeding-stuffs. The extent to which the third measure, a compulsory reduction in the live-stock population, would be necessary would then clearly depend on the level at which feeding-stuffs imports could be maintained during the War period. Up to the present, the supplies which have been released by the Ministry of Food have not fallen below the 50 per cent level, though the first preference accorded to certain classes of stock, notably milking cattle, has involved particular hardship on many breeders of pigs and poultry. If imports were to fall consistently below the 50 per cent level, a reduction in the live-stock population would be inevitable, for there is no more wasteful method of utilizing feeding-stuffs than by dissipating them in the maintenance of an excessive live-stock population.

In deciding on the classes of stock to be reduced, and on the extent of such reductions, a number of factors would require to be taken into account. Among these would be the relative food values, for the human population, of the various animal products produced by each class of stock, the extent to which the imports of such animal products were themselves reduced, the relative efficiencies with which the different classes of stock could convert feeding-stuffs into human food, and finally the maximum rates of reproduction and therefore the potential rates of replacement of the depleted flocks and herds in the post-War period. Any detailed discussion of these points would, however, be outside the scope of the present article.

CHEMISTRY AND HYDROGRAPHY OF LAKES TANGANYIKA AND NYASA

By R. S. A. Beauchamp

"JOHN MURRAY" Expeditions to Lakes Tanganyika and Nyasa have recently been undertaken in order to discover the chemical and hydrographical conditions obtaining in deep tropical lakes, and in the hope of explaining the faunal peculiarities of Lake Tanganyika.

The lakes are situated south of the equator in the African Rift Valley; both are approximately 400 miles long and 30 miles wide. Their long axes lie north and south, and their maximum depths are approximately 1,400 m. and 800 m. respectively. Superficially, they appear to be similar, but their fauna and flora are very different[1]. Seventy-five per cent of the species which make up the fauna of Tanganyika are peculiar to that lake, whereas the majority of species in Nyasa are common to other African lakes, or of world-wide distribution. The species peculiar to Tanganyika, notably the molluscs, resemble in many respects marine species. This led to Moore's theory[2] that at one time Tanganyika was connected with the sea, but geological evidence is entirely opposed to this theory. Later, Cunnington suggested that during an arid period the Lake contained a greater concentration of salts which led to the evolution of species resembling marine types. The research expedition has suggested an alternative explanation (see later) and supplied evidence against Cunnington's theory. I have given an account of the hydrology of Lake Tanganyika elsewhere[3].

Certain generalizations must be made to give point to what follows. Apart from the geographical situation of a lake, which determines the average temperature of the water and the quantity of sunlight, the biological productivity of any lake is largely determined by the amounts of nutrient salts present in the surface waters. These salts are supplied by decomposition of the bottom deposits, and by inflowing streams. The relative importance of these two sources of supply will vary from lake to lake, but usually the bottom deposits are the most important source. This is particularly so in such lakes as Tanganyika and Nyasa, where the volume of the inflows is very small indeed as compared with the volume of the lake. In Tanganyika the annual inflow is approximately equal to one two-thousandth of the volume of the lake, in Nyasa to one six-hundredth. Hence the biological productivity of these two lakes is mainly determined by the supply and transport of salts originating from the bottom deposits. These salts can be of no use until they are brought to the surface, where they can be utilized by the phytoplankton.

In shallow lakes, currents caused by winds may lead to complete circulation and complete mixing of the bottom and surface water, but in deep lakes this can only occur during the winter, when the whole lake is brought to a uniform temperature; in very deep lakes complete circulation may never be brought about. During the summer, the surface waters on warming become less dense and remain on a discrete layer, the epilimnion, which lies on top of the deeper cooler layer, the hypolimnion. Little or no mixing may occur between these two layers, with the result that the salts in the epilimnion may become depleted by the phytoplankton, though considerable quantities may be present in the deeper water. Conversely, oxygen may be abundant in the epilimnion and completely absent in the hypolimnion. From this it is evident that the abundance of the phytoplankton, and the abundance and distribution of the zooplankton and bottom-living animals in deep lakes are determined by the degree to which the epi- and hypo-limnion are differentiated, and the length of time these layers are maintained. Tanganyika and Nyasa are markedly different in these respects.

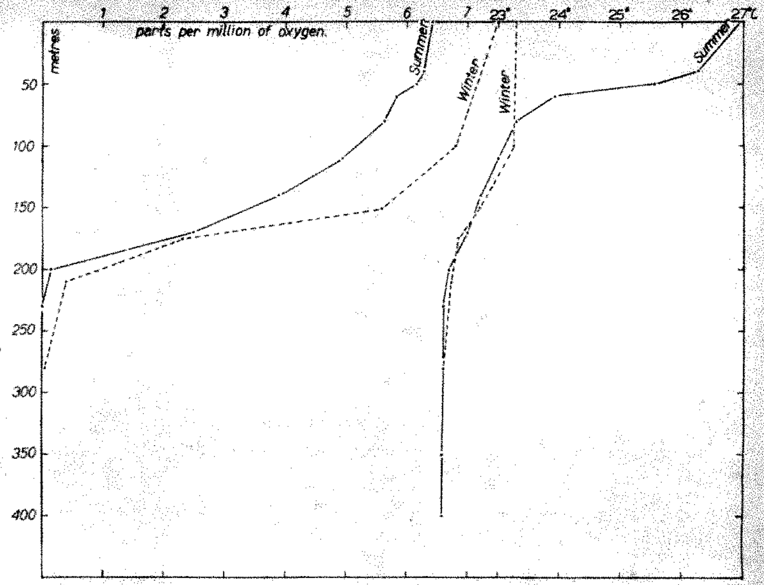

Fig. 2.

LAKE NYASA.

The position and extent of layers can be illustrated graphically by plotting the temperature and chemical composition of the water at various levels. The transition from one layer to the next is marked by sudden changes of temperature and in amounts of dissolved salts and oxygen. A discussion of the amounts of nutrient salts present in these two lakes is beyond the scope of this article; it must suffice to say that silicates may vary from 0·2 to 1·0 parts per million in the surface water, while the deep water may contain 20 parts, that corresponding differences occur in the amount of phosphates, nitrates, etc., and that the deep deoxygenated water contains considerable quantities of ammonia and hydrogen sulphide.

Figs. 1 and 2 show dissolved oxygen and temperature values for Tanganyika and Nyasa respectively. The continuous lines show values during the period of stability, the dotted lines during the period of maximum mixing. It can be seen that in the summer months there is a far greater temperature difference between the epi- and hypo-limnion in Nyasa than in Tanganyika, the deep water being one degree cooler, and the surface water on an average one degree warmer. In spite of this, considerably more mixing of the two layers occurs in Nyasa, as can be seen from the fact that oxygenated water has been carried down far below the thermocline, while in Tanganyika it does not penetrate below the thermocline. (The thermocline is the discontinuity layer between the epi- and hypo-limnion.)

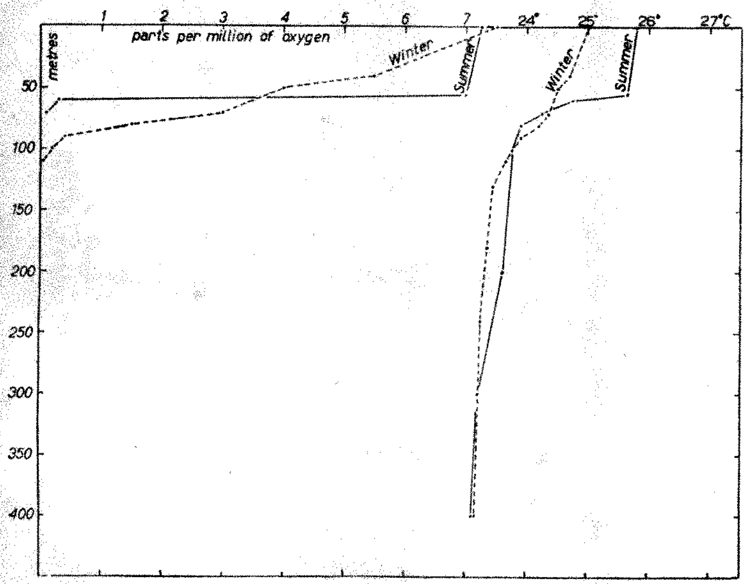

Fig. 1.

LAKE TANGANYIKA.

The explanation of this effect lies in the entirely different weather conditions which obtain in the two areas. In summer, Nyasa receives stronger and more variable winds, in winter much stronger winds than Tanganyika. This is because Nyasa lies farther south than Tanganyika, and nearer the coast, and so during winter (April to September), feels the full effect of the south-east trade winds. These, locally known as the *Mwera*, blow with extreme violence, often for days on end, though usually abating at night. Thus a high degree of mixing of water in the lake occurs throughout the winter, penetrating deeper as the temperature gradient is lowered. Tanganyika being farther north, and being protected by the Southern Highlands, does not receive the full force of these winds, and very much less mixing occurs. In the summer months both regions are characterized by thunderstorms and rain, with variable winds mainly from the north or north-east, but in Nyasa the winds are both stronger and more variable than in Tanganyika.

It has been shown[3] that sudden changes in wind direction cause more mixing than steady winds. When winds blow steadily over a lake, a current is formed which circulates in the epilimnion. This induces a secondary current in the hypolimnion; the two currents remain distinct, and, in the region of the thermocline, flow in the same direction, causing little or no mixing between these two layers of water. A sudden change in wind direction, however, will reverse the direction of rotation of the epilimnial current, with the result that it now opposes the hypolimnial current, causing turbulence at the thermocline, and mixing between epi- and hypo-limnion. Thus the constant changes of wind direction during summer cause in Nyasa a considerable amount of mixing in spite of the fact that the temperatures of epi- and hypo-limnion differ greatly.

It might seem that any oxygenated water which finds its way below the thermocline will become mixed with the whole of the hypolimnion. Actually, this is not the case. It was found on occasions that the hypolimnion was divided into two or more layers. This is a matter of extreme importance. If the available oxygen in the upper limits of the hypolimnion were to be distributed throughout the whole volume of the hypolimnion, it would be impossible to maintain an oxygen concentration in it sufficient to support the life of the deep-living animals. But as the available oxygen is only distributed through part of the hypolimnion, sufficiently high values are maintained in this part to support life.

Differences in temperature and chemical composition between layers in the hypolimnion may be slight, which makes them difficult to observe from a single set of samples. But these layers become distinct when values for dissolved oxygen on consecutive days are plotted on the same graph. This is because the currents in each of the various layers tend to make each layer more homogeneous. This shows as a decrease in the amount of dissolved oxygen in the upper portion of each layer and an increase in the lower portion on the later date. Fig. 3 shows this effect. It will be seen that the oxygen curve for February 23 repeatedly crosses the oxygen curve for February 21. The areas enclosed by these two curves indicate a decrease and increase in oxygen content in the upper and lower portions respectively of each layer. The upper 250 m. of the lake is clearly divided into four layers; this discontinuity between these layers being also shown by the temperature curve. The transfer of oxygen to lower levels is demonstrated, as we would naturally expect; this can only be done at the expense of the upper layers. It should be noted in this connexion that the surface waters of Nyasa during the summer contain less oxygen than those of Tanganyika. Later a change in wind direction upsets the layered condition described above, and mixing occurs between each of these layers. This layering of the hypolimnion had previously been suggested on theoretical grounds, but has not hitherto been so clearly demonstrated.

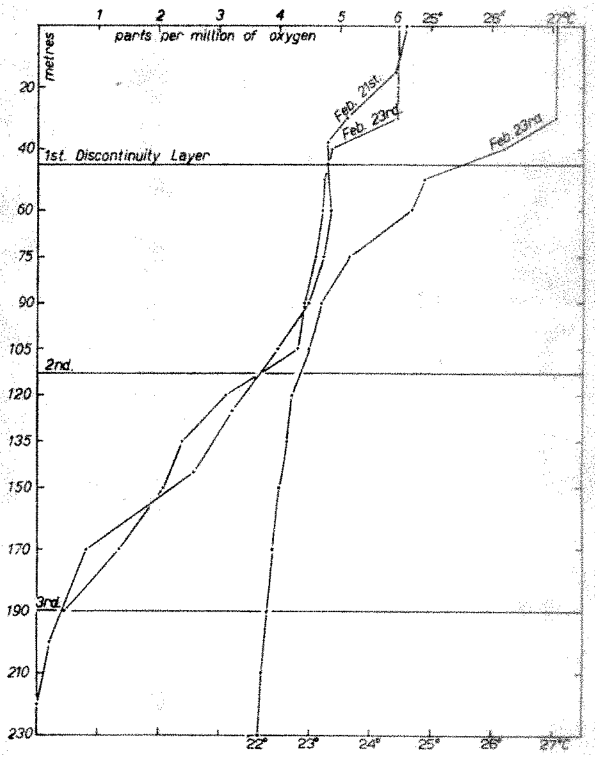

Fig. 3.

Space does not permit of details concerning the density of the plankton, or the length of the productive period in these two lakes, but as we would expect from the above data, Nyasa is a much more productive lake than Tanganyika. During the long period of stability in Tanganyika, plankton development is very greatly restricted. This is due apparently to a shortage of nutrient salts, probably nitrates in particular. At the end of the winter when mixing occurs, the phytoplankton starts to increase and is followed by an increase in zooplankton. In Nyasa, however, during the latter part of the winter when the *Mwera* is still blowing strongly, plankton development is slight, but as soon as the winds become less strong and a degree of stability is established, the plankton starts to increase rapidly. In this case it appears that plankton development is restricted, not by any shortage of salts, but by the too violent mixing of the surface waters. It may be supposed that phytoplankton is continually being carried down to depths in which photosynthesis is no longer possible. The evidence for this is not conclusive, but a parallel may perhaps be found in what occurs in the sea.

With regard to bottom-living fauna, Tanganyika cannot support an animal population below the level of the thermocline because of the lack of oxygen, but Nyasa does; notable among these forms are the Chironomidæ, which occur in enormous numbers. The adult Chironomids, on emergence, are swept into dense clouds and are carried often thousands of feet into the air by the 'thermals' which cause the offshore winds. These clouds of 'Kungen fly', as they are called, form a remarkable feature of Lake Nyasa, looking like two lines of bush fires occurring at intervals, along the length of the Lake seven to ten miles out from either coast. They usually appear very shortly after a period when mixing has led to an increase in the oxygen content of the deeper water. Sometimes these enormous swarms are blown on to the shore, when the natives, swinging baskets through them, collect enough of them to make compressed cakes, which are eaten with considerable relish.

Finally, certain peculiarities concerning the chemical composition of the waters of Tanganyika are important. It was found that the Lake contains relatively large amounts of potassium and magnesium. This is due partly to the natural accumulation of these salts, which is to be expected in a lake from which the main loss of water is by evaporation, and partly to the large amounts of these salts brought in by the Ruzizi. The Ruzizi flows into the north end of Tanganyika and is the outflow from Lake Kivu. These values, thirty-three and forty-four parts per million for potassium and magnesium respectively, may have caused the development of some of the species peculiar to this lake.

It was also found in Tanganyika that, though the total amounts of dissolved salts in the Lake are normal for fresh waters, the ratios of the amounts of magnesium to calcium and chloride to sulphate are high and resemble those found in sea water. As the inflowing waters do not show these proportions, they would seem to have been brought about by biological activity. For example, the molluscan fauna precipitates calcium, thus keeping its concentration low, while leaving magnesium to accumulate. Conversely, though this is certainly less important, the paucity of the flora, particularly the littoral flora, may result in an abnormally low rate of utilization of magnesium.

The high ratio of chloride to sulphate is not quite so simply explained. The low concentration of sulphate, which in the Lake is actually less than it is in the inflows, is presumably due to the removal of sulphur in the formation of all organic matter. On the other hand, though chlorides are essential for life, little chlorine is actually chemically combined to form organic matter. Hence chlorides are easily liberated from the bottom deposits. But sulphur, which is chemically combined in many proteins, is not easily liberated and appears mostly as hydrogen sulphide. Even then much of this hydrogen sulphide is probably precipitated again chemically as insoluble sulphides of copper and iron. Consequently, sulphates are continually being removed, either as undecomposed organic matter or as insoluble sulphides, while chlorides accumulate.

These and similar processes which alter the composition of lake waters occur to some extent in all lakes, but the extent to which they can be effective depends on the average length of time spent by water in the Lake. In Tanganyika this is an extremely long time, since the volume of the inflows is small compared with the volume of the Lake. In addition, the outlet from the Lake is small, and ninety per cent of the total inflow, including rainfall on the Lake, is lost by evaporation.

Reasons have been given[3] why the total concentration of salts in Tanganyika is no higher than four hundred parts per million, and why it is considered unlikely that the total concentration was at any time in the past considerably higher than at the present time. I suggest, however, that one of the causes for the marine appearance of a large number of the species found in Tanganyika may be due to the fact that in the Lake the ratios of chloride to sulphate and magnesium to calcium have become similar to those found in sea water. This theory will seem more convincing if a complete analysis of water from Lake Nyasa shows a more usual proportion of these salts. It is hoped that it will be possible later to have these analyses done by the Government Chemist, who kindly carried out the full analyses of samples from Lake Tanganyika.

OBITUARIES

Sir George Macdonald, K.C.B., F.B.A.

We regret to record the death of Sir George Macdonald, the distinguished Scottish archæologist, which took place in Edinburgh on August 9 at the age of seventy-eight.

George Macdonald was born at Elgin in 1862, and was educated at Kelvinside Academy and in the University of Glasgow whence, winning the Ferguson scholarship for classics, he passed to Balliol College, Oxford, and graduated with first-class honours in Classical Moderations and Literæ Humaniores. For a few years he was engaged in teaching at Kelvinside Academy. In 1892 he became lecturer in Greek in the University of Glasgow. It was during this period of work in Glasgow that he was attracted to the study of numismatics, and it was not long before he won recognition as an outstanding authority in this subject. For fifteen years he devoted himself to the preparation of a catalogue and the classification of the remarkable collection of coins of the Hunterian Museum. His work was recognized by the Académie des Inscriptions et Belles Lettres by the award, in 1907, of the Prix Allier de Hauteroche. He also became honorary curator of the Hunterian Museum and of the Society of Antiquaries of Scotland, and was elected an honorary member of the Viennese and American Numismatic Societies. His work and his conclusions are summed up in his Rhind lectures on coin types delivered in 1905. In 1913 he was awarded the medal of the Royal Numismatic Society, and in 1921 that of the American Numismatic Society.

Macdonald's pre-eminence as a student of numismatics, though widely recognized, was, after all, mainly of preponderant interest to specialists in that subject, except when, as it tended to do more and more as time went on, his studies impinged upon archæological and historical topics connected with earlier Britain. To both the learned and outside worlds he was known best as classical scholar, an authority on Roman Britain, and a motive force in Scottish education.

In 1904 Macdonald left Glasgow for Edinburgh, where he entered the Scottish Department of Education, of which he became permanent secretary in 1922, succeeding Sir John Struthers. He retired in 1928 after a term of office marked by great activity and advance in Scottish education.

It was in the study of Roman Britain that Macdonald made his most lasting contribution to archæology in the broader sense. His study of coins while at Glasgow had attracted him to the problems of Roman rule and culture. He devoted much study to the Antonine Wall between Forth and Clyde, and not only took part in many excavations himself, but also was largely responsible for the organization of the excavations on Roman sites in North Britain for a period of more than twenty years. To mention a few only of his numerous contributions to the literature of the subject, in 1907 he published a report on the Roman forts at Bar Hill, and in 1911 on the Roman Wall in Scotland. On the death of Prof. Haverfield he was responsible for revised editions of "The Romanization of Roman Britain" and "The Roman Occupation of Britain" by his fellow-worker.

During 1921–26 he was president of the Society for the Promotion of Roman Studies, and in 1928 president of the anthropological section of the British Association at the Glasgow meeting. He served on the Royal Commission on Museums and Galleries in 1927, and the Royal Fine Arts Commission of Scotland in the same year.

Mr. A. H. Case

The death on July 25 last, at the advanced age of eighty-two, of Mr. Albert Havelock Case removes a well-known personality from civil engineering circles in London. Mr. Case, who was a Whitworth Scholar, in addition to being a member of the Institution of Civil Engineers, received his early technical training in the old-established engineering firm of Stothert and Pitt, Ltd., of Bath. After some short service with the French State Railways, he was engaged on the staff of Sir John Coode in connexion with foreshore protection work at Spurn Point and Hastings. Then, under Sir John Wolfe Barry, he was resident engineer on dock constructional operations on the Tyne and in South Wales. Afterwards, he became engineer-in-chief of the Port Talbot Railway and Dock Company. During an association with Trinity House, he was resident engineer for the construction of Beachy Head Lighthouse, near Eastbourne. He also reported on the drainage of the Great Ouse basin.

By this time, Mr. Case was established in private consulting practice at Westminster, holding two appointments as engineer to Commissions of Sewers on the north side of the Thames. Later he was joined in partnership by Dr. Brysson Cunningham, with whom he carried out various land drainage and riverside works in south Essex and north Kent. The firm of Case and Cunningham also advised on port improvements at Montevideo, at Nassau and at Malta.

* * *

We regret to announce the following deaths:

Prof. G. H. Fowler, C.B.E., formerly assistant professor of zoology in University College, London, on August 15, aged seventy-nine.

Count Giovanni Lorenzini, president of the Italian Biochemical Institute at Milan, known for his work on the vitamins, on July 24.

Mr. R. C. Mossman, meteorologist of the Scottish National Antarctic Expedition; since 1920, climatologist to the Argentine Meteorological Office, on July 17, aged sixty-nine.

Mrs. Tyndall, widow of Prof. John Tyndall, on August 19, aged ninety-five.

NEWS AND VIEWS

Science in War Strategy

In his review of the war situation before the House of Commons on August 20, the Prime Minister said: "It is a conflict of strategy, of organization, of technical apparatus, science, mechanics and moral. . . . Moves are made upon the scientific and strategic boards, advantages are gained by mechanical means." On many occasions we have emphasized the all-important part which men of science must play (and, indeed, are playing) in this world conflict of ideals. Just as important is the fact that in most of his speeches and reviews, Mr. Churchill has revealed how alive he and the present Government are to the important contributions of science. "There seems to be every reason to believe that this new kind of war is well suited to the genius and the resources of the British nation and the British Empire." For several years now, Great Britain and the rest of the Empire (together with the United States and other democratic countries) have consistently offered hospitality and opportunity for work to thousands of the victims of the hideous Nazi racial laws. These included many men of science. The ultimate benefit to the cultural life of democratic countries had never needed emphasizing. It was immediate, and it will be lasting. Now the immediate benefit is becoming more and more evident and was stressed by the Prime Minister when he said: "Since the Germans drove out the Jews and lowered their technical standards, our science is definitely ahead of theirs."

Food Policy

The points raised in the leading article beginning on p. 243 have received the fullest support in the Prime Minister's speech. Germany has command of huge food supplies within her own frontiers and in the occupied territories. "The only agencies which can create famine in any part of Europe now and during the coming winter will be German exactions or German failure to distribute the supplies which they command." Furthermore, many valuable foodstuffs, such as fats, potatoes, milk, and so forth, can be used in the manufacture of war materials, such as explosives, motor spirit and plastics. Aid for any stricken country is therefore unthinkable while that country is under German control. This is, of course, a harsh policy to adopt, but it is an essential one. It can be offset, however, as pointed out in the leading article, by reserving foods in preparation for reconstruction after the War. We are now assured that this will be done by the Prime Minister who has said "we can, and we will, arrange in advance for the speedy entry of food into any part of the enslaved area when this part has been wholly cleared of German forces and has genuinely regained its freedom. We shall do our best to encourage the building up of reserves of food all over the world so that there will always be held up before the eyes of the peoples of Europe, including—I say it deliberately—the German and Austrian peoples, the certainty that the shattering of the Nazi power will bring to them all immediate food, freedom, and peace".

Man-power of the Nation

Some words uttered by Sir William Beveridge in the course of a broadcast address on the recent Industrial Registration Order referring to engineers are applicable outside the strict context of the address. He emphasized that registration does not mean that workers will be taken off their jobs immediately and put to other jobs. The first object of registration is to obtain a survey of the position so far as available man-power is concerned. Having obtained such a statement, it is possible to consider the re-allocation of individuals in such a way that the war-time needs of the nation receive first consideration. Sir William also pointed out that, even after this survey, many workers will of necessity still be left in jobs which are not obviously of direct use in the national effort. "If after registration we leave a man where he is, he can feel satisfied that he is doing his duty there," Sir William said, and that must be the consolation of many who are denied more spectacular achievement. This Industrial Registration Order is "part of a general plan to ensure that all the brains and muscles of the nation are used in the right way, so that there is no waste and no injustice". Such a general plan will command widespread support, the only regret being that it was not initiated many months ago before the present intense stage of the conflict had been reached. It should be carried through speedily and put into effect at the earliest possible moment.

Political Issues in India

Those, if any there be, who may feel surprised at the reluctant, not to say sluggish, reaction of opinion in India to the terms of the Viceroy's proclamation on present and future conditions affecting the constitutional issue, will do well to examine with care the masterly and statesmanlike analysis of the elements of the deadlock and the effect of the Viceroy's proposals, both now and as regards the future, presented to the House of Commons on August 14 by Mr. L. S. Amery, Secretary of State for India. The differences, as he pointed out, are not between the British Government and the Indians, but those which exist among the Indians themselves —on one side, the Congress party, which has sought to make itself the national party, and would wish to speak for India as a whole; on the other, to name the three elements only to which Mr. Amery referred, the ninety million Moslems, the scheduled castes who stand outside the main Hindu community represented by Congress, and thirdly, the Indian princes whose territory covers a third of all India. These differences are based upon a long and powerful tradition rooted in religious belief and social regulation. They are, Mr. Amery said in speaking more particularly of the Muhammadans, "as deep as, if not deeper, than any similar differences in Europe". Because they impinge upon what is most vital in the life of the people, namely, their religious beliefs and cultural beliefs, and because they are faced with the familiar urge of Hinduism to absorb and assimilate, they emerge in the form of a profound mistrust of majority rule.

Mr. Amery himself does not despair of the situation. As he told the House, he does not regard the differences between these conflicting elements in India, which have been the subject of negotiation since October last, as unbridgable. That in actual practice they may be bridged is shown by the co-operation of individual members of the Moslem community, who have taken an active part in the work of the Congress party. In the main, however, he relied upon two factors. In the first place, whatever may be the barriers between the component elements, India is a distinct cultural unity, a self-contained and distinctive region of the world, boasting an ancient civilization and a long history common to all her peoples, of which all Indians were equally proud; and secondly, all parties are at one in their detestation of Nazi aggression and their endorsement of our common cause. Common effort in the present emergency and the opportunity for discussion and the promotion of understanding pending post-War deliberations cannot but strengthen these two forces making for unity, and help to bring about that readiness to accept agreement based upon compromise of rule by consent which is "the foundation of all free government and of all true democracy". By India's aptitude in displaying these qualities in the immediate future will her full and free acceptance of the democratic ideal be judged.

Causes of Accidents in Factories

EVIDENCE submitted by the National Federation of Professional Workers before the Royal Commission on Workmen's Compensation on May 16 calls for a revision of the maximum benefits payable and attaches great importance to replacing the flat rate maximum by payments proportionately related to earnings already recognized in the payments for partial incapacity. It was also urged that there is no justification for such a salary limit as exists at present. The Federation expressed the opinion that extension of the salary limit or its entire elimination would not upset the structure or balance of the Act. It was further urged that compulsory insurance should be extended to all classes of employment and the doctrine of common employment abolished as a defence against claims under the common law.

In a memorandum of evidence submitted it was stated that the majority of accidents in factories occur owing to the negligence of employees, and in an examination on this memorandum the representatives of the National Federation of Professional Workers stated that in many engineering concerns most of the accidents are due to negligence or, what was worse than negligence in a sense, some breach of statutory regulations or statutory duties. The failure of the material is often a matter of negligence at some more remote period and the Federation's conception of negligence was that it began in the Board Room. Breakdown of material, for example, could generally be attributed to failure to inspect sufficiently frequently, and in very busy works a good deal was taken for granted without inspection. It is considered that many safeguards could be arranged as an integral part in the design of the machine, and that is increasing in many makes of machinery. It was urged that much could be done in the drawing office rather than after the machine is installed to prevent accidents.

In explaining that the majority of accidents in factories occur owing to the negligence of employees, it was held that accidents are not caused by the negligence of the injured employee and this was linked up with the doctrine of common employment according to which where an injury arises owing to the negligence of a fellow employee the injured man cannot take an action. Apart from what one might call natural accidents it was safe to say that every accident occurs through some human agency. Much negligence, it was brought out in further evidence, was not necessarily culpable but might be due to fatigue. The Federation did not agree to a distinction between accidents due to the negligence of a manager or someone in special authority under a manager and accidents due to the negligence of the ordinary fellow worker. It is considered reasonable to hold the employer responsible for damages even when the negligence was not on the part of any official but on that of a fellow worker.

Blow-Guns for Clearing Away Dust in Factories

ACCIDENTS occur every year as the result of attempts to clear away dust, etc. by hand from moving machinery or electrical apparatus. Using rags or brushes for this purpose is often very dangerous. According to *Engineering* of July 26, pneumatic blow-guns are proving very useful for this purpose. They weigh only half a pound and are easily handled even in very awkward positions. The blow-gun is intended for use in workshops where compressed air is available, and below the hand-grips it has a hose connexion. The body is of aluminium and the renewable nozzle is of bronze. The nozzle can have a bore of $\frac{1}{16}$ in., $\frac{1}{8}$ in. or $\frac{5}{32}$ in., as desired. If used near live electrical fittings, it is made of insulating material so that safe operation is assured if accidental contact is made. Control of the air jet is effected by a push button actuated by the forefinger of the hand holding the gun. The valve is readily renewable.

It is stated that the blow-gun has proved most useful in blowing dust from foundry moulds and is particularly effective in getting rid of the dust formed in machining operations in non-metallic materials, such as plastics, this dust being difficult to displace by means of brushes or rags. In wood-working machinery it is very useful in removing sawdust and shavings. To enable the gun to be readily connected to existing air supplies, the manufacturers have developed a neat pressure-reducing tube valve manufactured from bronze pressings and having a diaphragm of the oil-resisting rubber insertion type. The valve will reduce an initial pressure of 150 lb. per sq. in. to any pressure between 5 lb. and 100 lb. per sq. in., the adjustment being made by a thumb screw. The valve has a nickel-plated finish and is stated to be unaffected by oil or water and does not vibrate or chatter when in use.

War, Tradition and Natural Beauty

IN a war, which in so far as the greater includes the less, is being fought by the British people in defence of an ideal of the spirit which, we maintain, has run like a thread throughout our history, it is vital that every effort should be made to keep alive, even if necessary in attenuated form, activities which make for the preservation of the national tradition as embodied in our antiquities and places of historic interest, or in those vistas of our landscape which are not only beautiful in themselves, but also express something which is essentially in harmony with characteristics of the mentality of the British peoples. The recent pronouncement of the Council for the Preservation of Rural England makes a bold bid to reconcile claims arising out of present necessities with its objective of saving rural beauties from desecration.

How difficult this may become is strikingly illustrated in the recently issued report for 1939–40 of the National Trust. Here and there in the brief notes on the properties held by the Trust a hint is given of the difficulties which are being, or have had to be, overcome by those responsible for carrying out the objects of the Trust in securing that these objects shall not be irrevocably overridden, if that is at all possible, by the requirements of military authority or the necessities of food supply. The normal expansion of the work of the Trust cannot be expected to continue unimpaired in present conditions; and indeed the annual report for the period under review chronicles a reduction in receipts, not, indeed, as great as might be anticipated, which will make the realization of even working costs a matter of some anxiety. The work of the Trust, however, is, as has been said, of vital importance in maintaining much that is of the best in the national tradition, and its claims to public support should be among the last to be overlooked. An indication of the activity of the Trust in recent years is afforded by a comparative table given in the annual report, which shows that in the period 1914–40 there has been a tenfold increase in most of the figures. The number of properties has increased from 63 to 410, the acreage from 5,814 to 58,900; the capital raised and expended from £59,861 to £530,114, subscriptions from £559 to £6,193, and the gross income from properties from £1,461 to £27,553.

Preserves from the Garden

"GROWMORE" BULLETIN No. 3, of the Ministry of Agriculture and Fisheries (H.M. Stationery Office, 4*d.*), presents in a concise and practical form instruction for the housewife in the preservation of surplus fruit and vegetables for winter use. Full directions are given for the making of jams, fruit jellies, cheeses, and syrups, and the bottling and canning of fruit and vegetables. Instructive notes are provided on the peculiarities of particular fruits and their suitability for the various methods of preservation. A selection of recipes for jam and jelly made from the more important fruits is included, and in some of these the normal amount of sugar has been reduced to meet the difficulties of sugar shortage. A useful feature is a statement of the expected yield of jam from the amounts of fruit used. Various methods are given for sterilizing fruit for canning and bottling and the preservation of fruit in the form of pulp. The latter is a useful method for the storage of large quantities of apples and plums without sugar.

The preservation of vegetables is not so widely practised as that of fruit, and as pressure cookers are recommended for vegetable sterilization, this method will not be extensively used in the average household Several vegetables may, however, be preserved by pickling, which is briefly dealt with in the bulletin. Salted runner beans are invariably satisfactory, and as salt is cheap and the method simple, more use should be made of this usually prolific crop. Many fruits and vegetables can be dried for future use, a method which needs no preservative, and is adequately treated in this bulletin. The authors, Alice Crang and Margery Mason, have produced a very usable handbook, and are to be congratulated on the selection of the most useful and straightforward methods, as well as on the omission of technical details which are of little interest to the average housewife.

Organized Labour in Germany

ALTHOUGH written rather as if to prove a point, Dr. W. A. Robson's pamphlet, "Labour under Nazi Rule" (Oxford Pamphlets on World Affairs, No. 33. Pp. 32. Oxford: Clarendon Press. 3*d.* net) gives a concise and lucid account of the sweeping changes made by the Nazi regime in the status and organization of labour, from the liquidation of the highly progressive German working-class movement in 1933 to the system of unmitigated industrial conscription introduced since 1938. Prior to 1933, Germany was one of the most progressive countries in the world so far as the position of organized labour was concerned. By showing the extent to which industrial servitude and regimentation have been exacted as the price of Hitler's achievement in abolishing unemployment, Dr. Robson puts that achievement in its true perspective along with the Labour Front and the 'Strength through Joy' movement. This admirably written account of the present position of organized labour in Germany and the way in which it has arisen fully substantiates Dr. Robson's central thesis that the status, freedom, power, and conditions of work of the employed workers in Germany have deteriorated to an almost inconceivable extent under the Nazi Government.

Supply of Electric Torches

THE supply of pocket torches for the coming winter months is already being discussed by wholesalers and manufacturers. According to the *Electrical Times* of August 15, the evidence as to shortage or abundance is conflicting. Manufacturers at present are said to be rationing supplies to the wholesalers rather severely. American torches are difficult to obtain owing to import licences being withheld. Belgian and Dutch torches have disappeared completely. Any bulk supplies received are got rid of very readily. The public grew so accustomed to using these handy little accessories last winter that they are now buying them quite briskly although the long summer daylight hours render them unnecessary. Many hope that the various restrictions will be relaxed with the approach of winter. If this happens, the machinery of home production has been increased so extensively that maintenance of a steady and adequate supply will become possible. Much depends upon the Government's attitude towards raw materials. This authority urges the public to hold off purchasing until the late autumn, for batteries are not things that can be held in store without rapid deterioration, especially if kept in damp places. Others hold a more optimistic view. They point to the great strides taken by manufacturers to increase production to such an extent that the disappearance of foreign-made torches will more than be made good before next winter sets in. Supply firms, it is reported, are confident that the rush demand of last winter will be less severe and that all wants will be steadily met although there will be a slight increase in price.

Greenkeeping Matters and the Gall Midge of Grasses

THE Board of Greenkeeping Research has adapted its research station at St. Ives, Bingley, Yorks., to war-time conditions. Some of its new activities have already been mentioned in these pages, and the first war-time number of the Board's *Journal of Greenkeeping Research* (6, No. 21, from the Director, price 3*s*. 9*d*. per copy post paid) contains a number of short papers which deal further with the altered needs of the present time. The Station's director, Mr. R. B. Dawson, outlines the general war-time policy of linking golf grounds with food production so far as possible, and Mr. R. B. Ferro describes "War-time Turf Policy" from the point of view of minimal attention without permanent damage. There is a very useful survey of gall midge damage to grass seed by Mr. H. F. Barnes of Rothamsted Experimental Station. Many species, mostly of the genera Dasyneura and Contarinia, are shown to have specialized relations with a number of separate grass hosts. The damage done to seed plots must be very great, but seedsmen are now willing to pay more attention to their crops. Mr. Barnes considers the possibility of biological control through the selection of early or late maturing strains of the various host grasses to avoid the period of egg-laying. The present number of the *Journal* also contains notes and abstracts of a number of papers and matters of interest to those who have to deal with grassland.

Swordfish Attacking Vessels

SINCE the seventeenth century, authentic accounts are on record of the spearing of ships by the swordfish (Xiphias) and its relatives the spear- or marlin-spike-fishes (Makaira) and the sail-fishes (Istiophorus). The stories of these attacks, their effects and their causes, with much incidental information, have been gathered together and discussed in a 100-page monograph, illustrated by seven plates and several text-figures, by Dr. E. W. Gudger (*Mem. Roy. Asiatic Soc. Bengal*, 12, 215–315; 1940). The attacks, which have occurred in all parts of tropical seas, are delivered with force, for not only have ships been shaken from stem to stern by the blow, but also the penetrations recorded include the piercing of the copper covering, a 4-inch birch plank, and 6 inches of the timbers of the brig *Tinker* of New York, and the remarkable case of the South Seas whaler *Fortune* of Plymouth, Mass., the timbers of which beneath their copper sheath were penetrated through 18·5 inches of hard wood, 14·5 inches being of dense oak. The speed of the swordfishes is, however, great, and that together with the size of the fish, which may weigh 1,200 lb. (Zane Grey's marlin), and the fine lines of the sword itself, accounts for the power and effect of the blow. The author describes the fishes as timid rather than pugnacious, and concludes that the attacks are generally made either by fishes which have been wounded and are dashing about in pain and fright, or inadvertently when the fishes are, particularly in darkness, following and attacking a shoal of fishes upon which they are preying.

High-Speed X-Ray Photography

SHADOW photographs taken with an exposure short enough to show a moving bullet while passing through a block of wood were shown and discussed at a meeting of the American Physical Society held on June 21. According to a Science Service report, the photographs were taken by using a very brief electrical surge of high voltage and amperage got by charging a condenser in several seconds, and then discharging it through the X-ray tube. For the short space of time necessary to take the photograph, the new tube will carry a current of about 2,000 amperes at 100,000 volts. In photographing rapidly moving objects, a fine tungsten wire connected in the timing circuit is broken by the moving object so that the energy stored in the condensers is released at the correct instant. Possible applications discussed were the use of the method to study internal strains in rapidly moving machine parts and in the bones of the body in vigorous action. The new X-ray tube and technique have been developed in the Westinghouse Lamp Division by Dr. C. M. Slack and his associates.

T'ang Pottery for the British Museum

A REMARKABLE example of T'ang pottery, well known to collectors and students, from the collection of the late Mr. George Eumorfopoulos, has been given to the British Museum by his widow to mark his long and close friendship for that institution, of which he was a generous benefactor. The gift is a pottery model of a saddled horse. It stands just under a foot high, and is an outstanding example of the technical skill and artistic feeling of the Chinese under the T'ang dynasty. This period (A.D. 618–905) was one of the most remarkable in the history of the Chinese Empire. A consolidation and expansion of the imperial power after a time of stress, combined with a revival in the spirit of Buddhism, inspired from its sources in India by the pilgrimages of Chinese priests, to give birth to a remarkable achievement in all forms of the plastic arts, but more notably as exemplified in pottery figures from tomb burials and in the paintings such as those collected in large numbers by Sir Aurel Stein and those who, after him, visited the Buddhist cave shrines of Tun-Huang. The piece of pottery which has now been given to the British Museum was for long highly prized by its former owner and was his favourite specimen. It is known as the 'Blue Horse' on account of the extensive splashing of blue on its glaze, which makes it unique among figures from the tomb burials which are the main source of our knowledge of this type of art in the period.

Racial Characters in Ancient India

EXAMINATION of a skull from Chanhu-Daro, a site of the Indus Valley civilization in northern India, by Dr. Wilton M. Krogman, of the University of Chicago, it is stated in a communication circulated by Science Service of Washington, has demonstrated a combination of characters more usually to be assigned to diverse racial types. The skull in question is that of a young female and had been placed in a jar after decapitation. It is thought that it may have been that of a princess or priestess. It was found in the course of the excavations now being carried out by an expedition of the Boston Museum of Fine Arts, and has been dated as belonging to a period some five thousand years ago. Dr. Krogman's report indicates a combination of such negroid characters as a flattened head vault, broad nose opening and low eye-sockets with Caucasoid features such as narrow nasal bones, small teeth, and narrow distance between the eyes, as well as in the shape of the palate. His conclusion is that it represents "a proto-Mediterranean type in which ancestral negro traits have manifested themselves" and he goes on to suggest that the modern Mediterranean race may once have had a mixture of negroid blood which has since been eradicated.

Children under Foster Care

THE July number of the *Journal of Psychology* contains an interesting study of children under foster care by James W. Layman, of the Mental Health Service, Des Moines, Iowa, based on the examination of eighty-three children. Each of the homes to which the children were admitted was investigated with reference to its environment, physical condition, family history of both boarding parents, financial security of the home, family home life, interests and recreation. The original problems presented by the children included high frequency of lying, truancy, petty stealing, enuresis, timidity, aggressiveness, school maladjustment, larceny of motors, and housebreaking. The age of the children at the time of admission to the homes ranged from six to sixteen years. The outlook was most favourable in the case of the younger children, while the least favourable prognosis was presented by the older children in whom family backgrounds showed a high degree of instability.

Vital Statistics of the United States

THE summary of vital statistics of the United States for 1938, recently published (*Public Health Rep.*, 55, 933 ; 1940), gives the following information. There were 2,286,962 births and 1,381,391 deaths, giving a birth-rate of 17·6 and a death-rate of 10·6 per 1,000 population. Of the total deaths 116,702 were of infants less than one year of age, giving an infantile mortality of 51·0 per 1,000 live births. There were 25,644 sets of twins, 262 sets of triplets and 1 set of quadruplets as compared with 24,881, 219 and 4 respectively in 1937. There was a net natural increase of 7·0 per 1,000 population, the largest since 1930. The infantile mortality rate has shown an interrupted decline from 68·7 in 1928 to 51·0 in 1938, while the maternal mortality rate has fallen continuously during the eleven-year period from 6·9 to 4·4. As regards the causes of death in infancy, premature births stand highest in the list, while pneumonia, diarrhœa and enteritis and congenital malformations come next in the order stated. The cancer death-rate in the United States has risen from 104·1 in 1934 and 112·0 in 1937 to 114·6 in 1938. The deaths from motor accidents in the United States in 1938 (23·5 per 100,000 population) was the lowest since 1923 (23·3). In 1937 the rate was 28·8.

Isis and *Osiris*

THE publication of *Isis*, an international and polyglot quarterly devoted to the history and philosophy of science, was begun in Belgium in 1912–13. Five issues had appeared when the publication was stopped by the German invasion. After the War, publication was continued, the journal being edited in the United States, but printed in Brussels, later in Bruges. In 1924, the History of Science Society was founded in Boston, Mass., in order to guarantee and promote the publication of *Isis*. During the past sixteen years, no less than twenty-five volumes of the journal have been published. With the invasion of Belgium this year, publication was again interrupted. The editor, Dr. George Sarton, Mass., informs us that No. 84 (completing vol. 31) of *Isis* and No. 85 (vol. 32) were ready for press, and it is hoped to issue at least No. 84 this year. Inquiries should be sent to the secretary-treasurer of the History of Science Society, Dr. H. R. Viets, 8 The Fenway, Boston, Mass. From 1941 on (vol. 33 ff.) *Isis* will be printed in the United States. The first American number will include a list of all the papers and reviews which were to have appeared in No. 84 and vol. 32. *Isis* as prepared in America will probably be smaller than that of its Belgian predecessor, but the editorial policy will remain essentially the same. As regards *Osiris*, which was founded in 1936 in order to relieve *Isis* of the longer papers, it is not supported by the History of Science Society, and hence subscriptions to it or correspondence relative to it should not be addressed to the Secretary of the Society, but to Dr. Alexander Pogo (Harvard Library, 189, Cambridge, Mass.). At the time of the German invasion of Belgium, two volumes of *Osiris* were being printed, namely, vol. 8, dedicated to Paul Ver Eecke, historian of Greek mathematics, and vol. 9, dedicated to Max Meyerhof, historian of Arabian medicine. These two volumes will appear in due course. Vol. 7 is reviewed on p. 247 of this issue of NATURE.

July Earthquakes Registered at Kew

DURING July 1940 ten strong earthquakes were registered at Kew. Most of these were at a considerable distance, and five gave ground movement at Kew of greater amplitude than 10 μ. The greatest was on July 30, registered at 17m. 49s. past midnight G.M.T., which gave an amplitude of 45 μ at Kew. This shock had an epicentre some 3,020 km. distant from Kew and was the earthquake near Yozgad in Turkey (NATURE, August 10, p. 196). The earthquake with the greatest depth of focus which occurred during the month was on July 10, with a provisionally estimated depth of 600 km.

Scholarships in Agriculture

ON the recommendation of the Agricultural Research Council, the following awards have been made by the Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland: Ivor Isaac, University College, Swansea, a three-year research scholarship in plant pathology; J. S. Perry, University College of North Wales, Bangor, a three-year research scholarship in zoology; D. McFarlane, Glasgow Veterinary College and University of Glasgow, a studentship for research in animal health.

Awards in Engineering

THE following scholarships for 1940 have been awarded by the Institution of Electrical Engineers: *Duddell Scholarship*, annual value £150, tenable for 3 years, to D. LaW. W. King (Northampton Polytechnic); *Silvanus Thompson Scholarship*, annual value £100, plus tuition fees, tenable for 2 years, 1938 award to H. Darnell (University of Liverpool) renewed for a third year, no new award made this year; *William Beedie Esson Scholarship*, annual value £100, plus tuition fees, tenable for 2 years, renewable in approved cases for a third year, C. H. Bickerdike (London and North Eastern Railway Co.); *David Hughes Scholarship*, value £100, tenable for 1 year, J. H. Nicoll (Merchant Venturers' Technical College, Bristol); *Salomons Scholarships*, value £60, tenable for 1 year, H. H. Rosenbrock (University College, London); value £40, tenable for 1 year, P. H. W. Whyman (University College, London); *Thorrowgood Scholarships*, annual value £12 10s. each, tenable for 2 years, R. J. Post (London Passenger Transport Board), R. P. Gasson (Southern Railway Co.). No award of the Ferranti or Swan Memorial Scholarships or of grants from the War Thanksgiving Education and Research Fund have been made this year.

The following awards have been made by the North East Coast Institution of Engineers and Shipbuilders: Institution Scholarship (£100) to Ian Welsh Goodlet, an apprentice of Messrs. R. & W. Hawthorn, Leslie & Co., Ltd., St. Peter's Works, Newcastle-on-Tyne; bursary of £50 to Eric William Simpson, an apprentice of Messrs. A. Reyrolle & Co., Ltd., Hebburn-on-Tyne; M. C. James Medal to Mr. H. J. Tapsell, of the National Physical Laboratory, for his paper on "Creep at High Temperatures"; Thomas Fenwick Reed Medal to Mr. Harry Chilton, now at sea, previously with North Eastern Marine Engineering Co. (1938) Ltd., Sunderland (awarded biennially in recognition of evidence of ability to take a share in the control of industry); R. L. Weighton Medal to Wilfred Bailey, on the result of the Durham final engineering degree examination at King's College, Newcastle-upon-Tyne.

Announcements

THE title of professor of physics applied to medicine in the University of London, with the status and designation of appointed teacher, has been conferred on Dr. W. V. Mayneord in respect of the post held by him at the Royal Cancer Hospital (Free).

PROF. H. VINCENT, professor of epidemiology in the Collège de France, formerly inspector-general of the Health Service of the French Army, has been elected vice-president of the Paris Academy of Sciences.

DR. H. MARK, formerly professor of physical chemistry in the University of Vienna, has been appointed professor of organic chemistry in the Polytechnic Institute of Brooklyn. He will direct research in the field of high molecular weight compounds.

AT a meeting of the Society of Experimental Psychology recently held at the University of Pennsylvania, the Howard Crosby Warren Medal, which is given annually by the Society for outstanding research in the field of experimental psychology, was awarded to Ernest R. Hilgard of Stanford University, for his analysis of the conditioned response and his demonstration of its integration with the verbal and volitional processes in learning and retention.

BY acquiring the 335,000 Jews of the Baltic States the Soviet Union now has the largest Jewish population in the world, 4,835,000, made up approximately as follows: Russia proper, 3,050,000; Soviet Poland, 1,250,000; Bessarabia, 200,000; Baltic States, 335,000.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Polarization of Electrons by Double Scattering

THE general theory of the polarization of electrons by double scattering has been given by Mott[1], but detailed calculation of the percentage asymmetry to be expected in the azimuthal distribution after the second scattering at 90° has only been carried out for scattering fields of pure Coulomb type. In view of the fact that experiments have so far revealed no appreciable asymmetry under conditions when an appreciable percentage effect would be expected (for scattering of 79 kv. electrons by gold)[2], it is important that detailed analysis of expected effects for other types of scattering field should be carried out.

We have investigated the polarization effects arising from scattering by the atomic fields of gold, xenon and krypton (that is, screened Coulomb fields) for a wide range of electron energies (100 ev.–150,000 ev.). The differential equations involved have been solved in many cases by exact numerical integration and in other cases by use of Jeffreys' approximation[3], the validity of the latter having been first established. It is found that, in the energy range covered by Mott's calculations for the unscreened field of the gold nucleus, introduction of screening has no important influence, and the failure to obtain the predicted asymmetry remains unexplained.

An interesting effect of the screening is to make possible, in scattering by gold, the existence of large polarization in small energy ranges at low energies (of the order of a few hundred electron volts). Although the precise energy ranges in which these effects occur cannot be determined accurately by the theory, their existence can be demonstrated in the following manner. The percentage asymmetry involves the ratio of an asymmetry factor to a term which is proportional to the intensity of single scattering at 90°. In a screened Coulomb field, unlike an unscreened one, the latter term varies in an irregular manner with electron energy up to energies of some thousands of electron volts. In particular, for certain narrow electron energy ranges, it falls to very low values, as revealed from the experiments of Arnot on electron scattering in mercury vapour[4]. The asymmetry factor, on the other hand, does not vary so markedly. It is determined largely by the phase difference χ_1 at infinity between the wave functions for the $p\frac{1}{2}$ and $p\frac{3}{2}$ electrons. This we find remains, for gold, between 0·24 and 0·34 radians over an energy range of 250 ev.–100,000 ev. It follows, then, that at energies for which the single scattering at 90° is at a minimum value, the percentage asymmetry may be quite large. Owing to its association with low intensity of total scattering, it will be difficult to detect this experimentally, although there are advantages in using the lower energy electrons involved. Calculations reveal that for xenon and krypton the values of χ_1 are insufficient to give appreciable polarization at any energy.

As a further type of scattering field, as far removed from the Coulomb type as possible, we have considered the spherical potential well. This also is found to give rise to polarization effects, which tend to occur in narrower energy regions than for a Coulomb field.

Details of the investigation, together with its bearing on the nature of the modifications of the interaction energy between an electron and an atomic nucleus necessary to reduce the theoretical polarization, will be published in the *Proceedings of the Royal Society* when circumstances permit.

Derivation of Einstein Effect from Eclipse Observations of 1936

THE total solar eclipse of June 19, 1936, gave Japanese astronomers an excellent opportunity for solar research. The central line ran just parallel to the north-eastern coast of Hokkaido, facing Okhotsk Sea. More than twenty sites were occupied by Japanese and visiting observing parties. Our party, being the expedition from the Tôhoku Imperial University at Sendai, decided to make observations at Kosimizu, the co-ordinates of which are:

astronomical longitude: 144° 28′ 3″ E.
= 9h. 37m. 52·2s. E.
astronomical latitude: 43° 51′ 21″ N.

Our observing programme was mainly directed towards testing the Einstein effect. For this purpose, a special lens was made by Nippon Kogaku Kogyo K. K. (Japan Optical Industry Company, Limited) with aperture 20 cm. and focal length 500 cm. This lens was used horizontally with one cœlostat mirror.

The plate used was "Oriental 1200", size 25 cm. × 30 cm., thus covering a sky field of 2·9° × 3·4°. Duration of totality was 109 seconds, and during that time only one plate was taken with exposure of 80 seconds. Ten star images were recognized on the plate, but two of them were so near to the edges that they could not be measured.

After the lapse of about half a year, two comparison plates were taken at Sendai, not at Kosimizu. These comparison plates were called No. 115 and No. 119.

The plates were then brought to the Tokyo Astronomical Observatory. By the kindness of the staff of the Observatory, the use of the Zeiss blink microscope was given freely, and with that instrument the relative displacements of the star images on the eclipse plate and on one of the comparison plates were measured very accurately. These measurements were corrected for differential refraction, differential aberration and proper motion, and then reduced by the method of least squares. In doing so, the so-called "Entartung" problem discussed by Dr. Freundlich was not touched, and the usual method of six plate constants and Einstein constant was adopted. The observation equations run as follows :

$$A + Cx + Dy + Fx^2 + Gxy + E\frac{R_\odot}{r}\frac{x}{r} = \Delta x,$$

$$B + Cy - Dx + Fxy + Gy^2 + E\frac{R_\odot}{r}\frac{y}{r} = \Delta y.$$

Here x, y are in the increasing directions of right ascension and declination. By forming the normal equations, the six plate constants A, B, C, D, F, G and Einstein constant E were calculated, with the following results :

$E = 2{\cdot}13''$ .. .. Eclipse Plate—No. 115,
$E = 1{\cdot}28''$ .. .. Eclipse Plate—No. 119.

The details will in due course be published in Vol. 18, No. 1 of the *Japanese Journal of Astronomy and Geophysics*.

Evaporation of Water through Multimolecular Films

Hedestrand[1], Rideal[2] and Langmuir[3] have shown that unimolecular films generally do not reduce evaporation from water surfaces into air to an appreciable extent, the reason being that the evaporation resistance (the reciprocal of the evaporation rate) of unimolecular films is of the same order as the evaporation resistance due to collisions of the evaporating molecules with air molecules and subsequent deflection to the water surface. The only exception is cetyl alcohol, which shows appreciable reduction ; we found that octadecyl alcohol behaves similarly to cetyl alcohol.

F. Sebba and H. V. A. Briscoe[4] have recently shown that unimolecular films may produce substantial reduction when they are compressed. They have also investigated a thick film of lubricating oil showing the first interference colours and found a reduction of only a few per cent. However, with films of much greater thickness they found appreciable reduction.

We have investigated the evaporation through layers of 0·5–5 μ thickness of paraffin oil, which were obtained by the aid of spreading agents. The research was undertaken with a view to practical application in the protection of dams, etc., in the arid areas of the interior of Australia. The laboratory conditions had, therefore, to be similar to natural conditions, and it was for this reason that evaporation in open Petri dishes was investigated. No particular difficulty is experienced in obtaining a film of about 1–2 μ thickness which will reduce evaporation by 50–60 per cent. The most successful films are those obtained from dilute solutions (for example, 1 : 50) of boiled linseed oil, stand oil, terebinth oil, or high boiling fractions of eucalyptus oil in white paraffin oil. On the other hand, simple fatty acids and alcohols, added to paraffin oil, may cause initial spreading, but the films are unstable and collect into lenses after some time. Lubricating oils also do not generally spread well, although they no doubt contain 'amphipathic' molecules as a consequence of oxidation of paraffins.

Particularly high reductions (up to 99 per cent) have been obtained with thin films (0·5–1·0 μ) of certain high boiling fractions of the neutral oil of vertical retort tar. All these observations relate to films on neutral water.

The problem of the stability of these multimolecular films of hydrocarbons, spread by amphipathic molecules adsorbed in the interface, is still obscure. The films deteriorate with time under present experimental conditions. This is probably due to dust settling on the surface. Addition of dust, unless it be purely siliceous, always reduces the effectiveness of the film. There are indications of chemical changes (for example, polymerization) of the spreader, especially in the case of linseed oil and stand oil. However, it is doubtful whether they are responsible to any considerable extent for the deterioration, for no such deterioration is found within two weeks with paraffin – stand oil films investigated in a desiccator, if the film thickness is greater than 1 μ. Thinner films, however, show deterioration even under these conditions. We are at present examining the question of stability more closely and we intend to investigate the thermodynamic conditions directly by determination of the spreading coefficients.

The influence of winds on multimolecular films is interesting. It has been found by experiments in a wind tunnel that the reduction of evaporation in a wind is greater than in still air. This apparently surprising result is, however, readily understandable, since the wind increases the rate of evaporation from the free surface more than from a film-covered surface. In other words, the air resistance is considerably lowered by the wind, whereas the film resistance is but little affected. This holds, of course, only so long as the continuity of the film is not seriously affected by the wind. Under laboratory conditions, the film remained effective even when air was blown directly against the surface by a fan. Under natural conditions, on the other hand, the position is more unfavourable as a consequence of the great areas involved. During experiments on a dam of approximately 300 square yards area, it was found that on windy days the film was blown right into a corner, although it usually spread again after the wind had subsided. The main difficulty with respect to dams is, however, due to the short life period (a few days) of the films under natural conditions, most probably as a consequence of the action of dust and suspended material.

We are greatly indebted to the trustees of the Science and Industry Endowment Fund of the Council for Scientific and Industrial Research of Australia for a research grant.

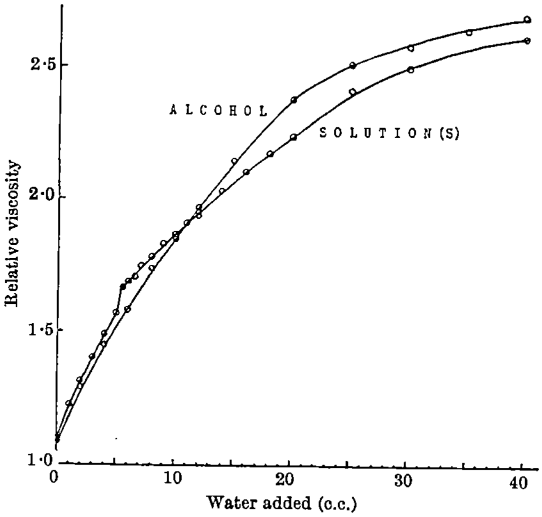
Binding of Water by Stearanilide

I HAVE suggested[1] that in the hydrated anilides of stearic and palmitic acids, the 'bound' water is held by a micellar structure. Some further evidence supporting this view has now been obtained.

Quantities (0–40 c.c.) of distilled water were added to 50 c.c. samples of a 0·1 per cent solution of stearanilide in absolute alcohol (*S*). The mixtures were well shaken and allowed to stand for 20 hours. Mixtures containing 0–5·0 c.c. water were clear; slight opalescence developed in those containing 5·5–7·0 c.c. water; with more than 7 c.c. added water a white precipitate of hydrated stearanilide was formed. The bulk of precipitate increased gradually with the amount of water but became constant when this reached 15 c.c.; no further precipitation occurred on adding more water to the filtrates from solutions originally containing 15 c.c. or more of water.



Solutions containing a precipitate were filtered through sintered glass and the filtrates collected in dry vessels. The relative viscosities of all the solutions were then measured at 20° C., using a Höppler Viskosimeter. Afterwards the relative viscosities of a series of alcohol-water mixtures (prepared by adding 0–40 c.c. distilled water to 50 c.c. samples of absolute alcohol) were measured under the same conditions. In the accompanying graph are shown the viscosity changes brought about by adding water to 50 c.c. solution *S* and to 50 c.c. absolute alcohol.

Interpretation of these results may be attempted along the following lines: addition of water to solution *S* lowers the solubility of the stearanilide, but before precipitation occurs aggregation of the stearanilide molecules into micelles of colloidal dimensions takes place (this is shown by the development of opalescence and an abrupt increase in viscosity as the amount of added water is increased from 5·0 to 5·5 c.c.). Addition of more water has three effects: (1) hydration of the micelles in solution, (2) precipitation of hydrated stearanilide, (3) dilution of the intermicellar fluid. Factor (2), involving abstraction of water from the intermicellar fluid, tends to decrease viscosity and is operative in solutions containing 7–15 c.c. added water. Factor (3) has the opposite effect (the alcohol-water curve) and operates throughout the series. The influence of factor (1) on viscosity is obscure because two actions are opposed, namely, swelling of the micelles and removal of water from the intermicellar fluid. In the region where factors (1) and (3) only are in operation (that is, with 5·5–7·0 c.c. added water) the slow rise in viscosity suggests that the second action predominates.

The precipitation of hydrated stearanilide is complete when 15 c.c. water have been added to 50 c.c. solution *S*. At this stage the precipitated material contains about 95 per cent water of hydration as it floats in the liquid phase. This 'primary' bound water is difficult to remove by ordinary desiccation[1]. With the addition of water in excess of 15 c.c., further hydration of the precipitate takes place, as is shown by the widening of the gap between the two curves. Easily removed by ordinary drying methods, this 'secondary' bound water is probably held loosely on the outer surfaces of the swollen micelles. The amount of 'secondary' bound water taken up reaches a constant value when the quantity of water added to 50 c.c. solution *S* exceeds 30 c.c. (the attainment of complete hydration of the stearanilide is indicated by the two curves becoming parallel).

Does the Hypophysis Secrete a Pancreotropic Hormone?

EXPERIMENTS to determine whether the anterior pituitary lobe secretes a 'pancreotropic' hormone, that is, a hormone necessary for the maintenance and function of the pancreatic islets, have been made on the following lines:

(1) The pituitary gland was removed from a series of Wistar rats. The weight of the pancreas decreased, in proportion to the body weight, from an average of 0·57 gm./100 gm. of body-weight to 0·44 gm./100 gm. one month after hypophysectomy. At the same time the insulin extractable from this diminished pancreas was equal to or even greater than that of control animals, in proportion to the body weight[1,2]. Thus, 150 control rats contained 0·64 units of pancreatic insulin per 100 gm. of body-weight, while 77 animals weighing 118 gm. one month after hypophysectomy contained 0·62 u./100 gm., and 48 rats weighing 78 gm. under similar conditions contained 1·06 u./100 gm.

(2) When crude anterior pituitary extracts containing the pancreotropic factor[4] were administered to the hypophysectomized rat by injection, the relation of pancreatic insulin to the increased body-weight remained at or returned to the limits for control animals (0·69 u./100 gm. for thirty-five rats averaging 128 gm. at operation, and 0·58 u./100 gm. for thirty rats averaging 83 gm. at hypophysectomy).

(3) Implantation of tablets of œstrogen depresses growth by interfering with normal pituitary function. Under such conditions the size of the pancreas is not diminished in proportion to body weight and the insulin contained therein is significantly increased in

relation to the weight of the animals, as it tended to be after hypophysectomy (1·12 u./100 gm. in 41 rats 3–4 weeks after the subcutaneous implantation of two 15 mgm. tablets of stilbœstrol, and 1·01 u./100 gm. one month after implantation of one 12 mgm. tablet of œstrone). When rats carrying stilbœstrol tablets further received injections of crude anterior pituitary extract, the insulin increased in approximate proportion to the growing body-weight, remaining higher than in control rats (1·26 u./100 gm. for 42 rats after two weeks daily treatment with extract).

In order to demonstrate that the pituitary gland secretes a pancreotropic hormone it is necessary to show that removal of the gland results in a diminution in size and activity of the pancreatic islets (in proportion to the body weight) and that this condition may be cured or prevented by pituitary therapy. The evidence here presented does not support the assumption that the anterior pituitary lobe exerts a direct hormonic control over the islets of Langerhans, although extracts of this gland contain a pancreotropic substance capable of increasing the amount of islet tissue and of insulin, in the pancreas of the normal rat[3,4].

The results will be given in detail and discussed in a paper to be published by one of us (M. G.) in the *Journal of Endocrinology*. We wish to express our indebtedness to Messrs. Boots and Co. for the gift of stilbœstrol and for the preparation of the tablets.

Nature of Oxidative Phosphorylation in Brain Tissue

A CONNEXION between oxidation of pyruvic acid and esterification of inorganic phosphate with hexosemonophosphate to hexosediphosphate in brain preparations has been recently described[1]. I have now found that glucose can be substituted for hexosemonophosphate and the phosphorylation product is still hexosediphosphate. The necessity of 'adenine nucleotide' for the above reaction as well as the dependence of the oxidation on the presence of both 'adenine nucleotide' and inorganic phosphate[2] led to the assumption that the oxidation of pyruvic acid was linked up to a phosphorylation of adenylic acid to adenosinepolyphosphate, which would then transfer its labile phosphate groups to hexosemonophosphate or glucose. This is supported by the fact that either glucose or hexosemonophosphate can be phosphorylated to hexosediphosphate anærobically by transfer of phosphate from phosphopyruvic acid in the presence, but not in the absence, of adenylic acid. Half of the phosphopyruvate phosphate is set free and the other half is esterified with glucose or hexosemonophosphate. This is the same ratio as was found by Ostern, Guthke and Terszakovec[3] for the transfer of phosphate from adenosinetriphosphate to hexosemonophosphate in muscle extract. The phosphorylation of glucose under these conditions had not been so far observed in animal tissues.

The reactions taking place with glucose can be formulated as follows:

(1) 4 phosphopyruvic acid + 2 adenylic acid = 2 adenosinetriphosphate + 4 pyruvic acid.

(2) 2 adenosinetriphosphate + 1 glucose + 2 H_2O = 1 hexosediphosphate + 2 H_3PO_4 + 2 adenylic acid.

The sum of equations (1) and (2) is the overall reaction (3):

(3) 4 phosphopyruvic acid + 1 glucose + 2 H_2O = 1 hexosediphosphate + 2 H_3PO_4 + 4 pyruvic acid.

Recently Colowick, Welch and Cori[4] concluded that the oxidative phosphorylation of glucose in kidney extracts, previously studied by Kalckar[5], is linked up with the oxidation of succinic to fumaric acid. In brain dispersions oxidation of succinate does give rise to phosphorylation of glucose. However, if oxidation of the pyruvate—arising by subsequent oxidation of malate to oxaloacetate and breakdown of the latter—is checked by arsenite, the ratio atoms phosphorus esterified to molecules oxygen taken up is only about a half of that obtained when pyruvate is oxidized (in the absence of arsenite) as shown in the accompanying table. Arsenite, whilst fully inhibiting both oxidation of pyruvate and the accompanying phosphorylation, is without effect on the phosphorylation of glucose by transfer of phosphate from phosphopyruvic acid.

1·5 ml. dispersion from pigeon brain (dialysed 6·5 hours) to 2·3 ml. with additions including phosphate buffer *p*H 7·3 (0·025*M*), Mg^{++} (0·2 mgm.), adenylic acid (0·0007 *M*), glucose (10 mgm.), and NaF (0·02*M*). 35 min. in air at 38°. (O_2 uptake measured during the last 30 min.).

	No further addition	Na fumarate (0·005*M*) +Na pyruvate (0·013*M*)		Na succinate (0·03*M*)	
		No arsenite	0·008*M* Na arsenite	No arsenite	0·008*M* Na arsenite
µl O_2 uptake	0	320	19	276	178
mgm. P esterified	—	1·20	0·00	0·77	0·23
atoms P/mols O_2	—	2·78	0·00	2·01	0·94

The above suggests that the oxidative phosphorylation may be of a twofold nature; half of it being connected with the dehydrogenation of pyruvic acid as suggested previously[1], the other half with the transfer of hydrogen catalysed by dicarboxylic acids. This view would seem to be supported by the fact that when pyruvate is oxidized by brain dispersions, in the presence of fumarate, the P/O_2 ratio in the first few minutes is 4 atoms phosphorus to 1 molecule oxygen. It would be difficult to understand how the removal of 2H would give rise to an uptake higher than 1 atom phosphorus unless their further catalytic transfer is also linked up with phosphorylation.

I am indebted to Prof. R. A. Peters for his interest and to the Nuffield Trustees and the Rockefeller Foundation for grants in aid of this work.

Distribution of Ammonia in Larvæ of *Lucilia cuprina*

It has been established that sterile larvæ of *Lucilia sericata* excrete the bulk of their nitrogen in the form of ammonia[1,2]. Similar studies with larvæ of the Australian sheep blowfly, *L. cuprina*, support these findings. When reared on a medium composed of yeast, egg white and sodium chloride[3] the ammonia excretion per 100 larvæ increased after hatching until the larvæ were fully grown and then it diminished rapidly as they approached the pupal state.

This work has been extended to a microchemical study of the distribution of ammonia in the organs and tissues of larvæ of *L. cuprina*. For qualitative testing, mature larvæ were opened under isotonic saline (1·5 per cent sodium chloride). The saline was then removed and the reagent applied. Nessler's reagent and Riegler's reagent were each employed. The latter was prepared according to the directions of Feigl[4], saturated calcium hydroxide being used to render the solution alkaline.

For the quantitative study, the larvæ were reared on the artificial egg white – yeast medium containing 0·01 per cent brom cresol purple. As shown by Waterhouse[5], this indicator serves to define the acid mid-segment of the midgut. For each experiment, 10 larvæ were subdivided into the required portions. The dissections were performed under isotonic borax (2·5 per cent $Na_2B_4O_7$) to prevent the formation of ammonia during treatment and ammonia was estimated by adapting the permutit-Nessler method[6] to deal with micro quantities.

As shown in the accompanying table, the results obtained by the three methods agree fairly well.

Method	Fat body	Integument & skeletal muscle	Midgut			Hindgut		Malpighian tubes
			Anterior	Mid	Posterior	Anterior half	Posterior half	
Qualitative								
Nessler's Reagent	+	+	–	++	–	++	++++	+
Riegler's Reagent	+	+	–	++	–	+++	+++	+++
Quantitative mgm. per cent NH_3-N (Av. of 9 experiments)	21	3	11	27	4	206	544	77

These data help to elucidate the mechanism of ammonia formation and excretion in this organism. They are interpreted as showing that ammonia, produced in the midgut, is absorbed into the hæmocœle and transferred to the Malpighian tubes. The dilute ammonia solution, transmitted from the Malpighian tubes to the hindgut, is gradually concentrated by re-absorption of water as it moves along the hindgut towards the anus. This view of the mechanism of ammonia excretion, which implies that ammonia passes into the body cavity, is also supported by analyses of the hæmolymph, which contains 12 mgm. per cent NH_3-N. Acidity in the mid midgut would explain the high ammonia capacity of the gut contents in that region. Ammonia is occasionally detected in the crop if the diet has become rich in excreted ammonia.

Except in the alimentary canal and the Malpighian tubes, the ammonia concentration is relatively low. Some storage of ammonia occurs in a few cells of the fat body, and a portion resides in the integument, sometimes becoming visible as a thin brown line just beneath the cuticle when Nessler's reagent is applied.

A fuller discussion of this work will be published in Australia by the Council for Scientific and Industrial Research.[7]

Practical Science in Schools

I feel from my own teaching experience that practical work by pupils is essential in order to avoid that common type of 'learning' in which the pupil obtains credit for knowing work, and himself believes he knows it, merely because he is adept at quoting phrases of which he has not properly understood the meaning[1]. Recently the Spens Report has stressed the educational importance of 'activity' (that is, *use* of the pupil's knowledge and abilities), and of handwork. These imply that knowledge, if it is to last, must be tested and corrected by being put to practical use, and so converted into a habit; and that, in learning, the hand has an important part to play as an organ of sensation.

Would curtailment of practical work necessarily promote the consideration of social and humanistic contacts? I fear it would unconsciously encourage a dogmatic and authoritarian attitude, by removing that constant reference to observed fact which is the distinguishing mark of science. Since this experimental attitude permeates both the theoretical outlook of science and its technical use, it is an essential part of all its social values too.

If a science teacher asks himself, at each stage in his teaching, what aims he has in view, and applies an experimental outlook to the problem of how to achieve them, he will find that some traditional practical work can be omitted. But at the same time by watching how children react if allowed to do as they please with, for example, lenses, magnets, earthworms, mechanics apparatus (provided this is large enough for the forces to be felt by the organs with which we normally estimate forces—the sensory nerves of the muscles), he will find many suggestions for pupils' practical investigations bearing on everyday life, scientific method, applications of biology, local industry, etc.

With elementary classes one can often reduce expenditure by using robust commercial apparatus instead of fragile laboratory ware, commerical chemicals when pure ones are not needed, and the products of ordinary shops and of Nature whenever possible. This at the same time brings closer the social and humanistic contacts required.

RESEARCH ITEMS

Stone Implements from Canberra, Australia

The Canberra meeting of the Australian and New Zealand Association for the Advancement of Science was made the occasion by H. P. Moss of an exhibition and survey of aboriginal Stone Age material found in the Capital Territory (Report, 24th meeting, 1939). More than three hundred specimens were exhibited; with two exceptions, all were collected from the area constituting the City of Canberra, the author's first discovery being an axe-head found close to the Acton offices in 1919. At first sight the specimens, especially the scrapers and points, appear to suggest that there were two waves of Stone Age culture; the difference is to be explained by the fact that while much material was collected on ridges exposed to the winds as well as alternations of heat and cold, a considerable amount was recovered from depths ranging from two or three to six feet below the surface and had thus been protected against weathering. The depth of a find affords little criterion of age, as for example, in Crete, where twelve inches is estimated as the equivalent of a hundred years. In Canberra, high winds blowing continuously for a number of hours will cause a remarkable accumulation of sand deposit or an equally remarkable denudation. In regard to future investigation, at least five localities are indicated as worth examination in view of their suitability for aboriginal camps as regards both food supply (small game) and shelter from the prevailing wind.

Vaghers of Okhamandal

S. T. Moses, while acting as director of fisheries, Baroda State, was brought into intimate contact with the historic and interesting community of the Vaghers, for whose relief a pearl fishery was organized recently. Observations were made and anthropometric measurements taken (*J. Roy. Asiat. Soc. Bengal, Letters*, 5; 1939). They are undoubtedly among the earliest inhabitants of the Okhamandal district and are descended from the aboriginal inhabitants, the Kalas, one of the three tribes said to have sprung from the sweat of God. There has been great admixture, especially with races of Rajput origin. The first conqueror of the district was the king of the Yadavas, who was the eighth incarnation of Vishnu. The original occupation of the Vaghers was fishing, but they developed into a violent freebooting tribe, though authority has now persuaded them to take to agriculture, and many follow fishing, pearl-fishing and sailing as an additional occupation. Their speech is a jumble of Gujarati and Cutchi, a mongrel speech intelligible only after long residence. The men give a military salute instead of the more general salaam, while the women greet their relatives by cracking their fingers on the temples or on the head-scarf just above. In religion they are Hindus but, as is usual with many other Hindus, they go to the shrines of Muhammadan saints for the cure of diseases. Marriage, usually arranged by the parents, is preceded by a betrothal. The marriageable age is 15–20. The ceremonies differ in no way from those of surrounding castes, Brahmin priests officiating. Men seldom marry more than one wife and divorce is easy. The men are of medium stature, the range of variation being from 5 ft. 1 in. to 5 ft. 10 in., the cephalic index varying from 76·9 to 86·4.

Changes in the Colours of Birds

In order to define more accurately the changes in the colour of plumage due to the wearing and the fading of feathers, Frederick H. Test has studied the plumage of flickers (Colaptes) (*Condor*, **42**, 76; 1940). Exposure of several kinds of fresh feathers to sunlight for sixty-five days produced distinct fading. The carotenoid colours (reds and yellows) of all feathers except the red malars and nuchal crescent feathers were strongly affected; the latter type of red was apparently unaltered. The changes in colour probably result from slow oxidation under the influence of sunlight. The melanic hues (browns, blacks and greys) were only slightly affected by the exposure. These experimental changes correspond with the conditions found in breeding birds, the amount of change varying with the degree of exposure to sunlight. The changes seen in the melanic colours are principally due to a loss of pigment through abrasion. Black regions scarcely change, because loss of pigment is slight and such loss as occurs is imperceptible on account of the great concentration of black.

Induced Evolution through Chromosome Changes

A. F. Blakeslee, director of the Department of Genetics, Carnegie Institution of Washington, read a paper on induced evolution in plants through chromosome changes before the Eighth American Scientific Congress. Evolution of plant types is dependent upon changes in their chromosomes. In addition to changes in individual genes, gross changes in chromosome structure may be induced by X-rays, radium, heat and ageing seeds. Chromosomes may be broken and their parts interchanged (segmental interchange) or a part may be attached to the end of another chromosome (simple translocation). By treatment with heat or a number of different chemicals, notably colchicine, it is possible to induce the chromosomes to double in number. We now have the three following ways of making new species by laboratory methods: (1) Combining interchanged chromosomes in such a way that to the end of a chromosome there is added extra chromosomal material which brings about changes in the structure and appearance of the plant. This method is not yet known in Nature. (2) Interpolation of the extra material inside another chromosome. This method is suspected in Nature. (3) Doubling chromosome number in sterile species hybrids to produce new pure-breeding types with enhanced vigour. This method is known to have occurred in Nature both in the formation of wild species and in the production of superior varieties of cultivated plants.

Salivary Gland Chromosomes

A step towards the elucidation of chromosome structure has resulted from the treatment of salivary gland chromosomes by solutions varying in pH of 1–14. M. Calvin, M. Kodani, and R. Goldschmidt (*Proc. Nat. Acad. Sci.*, **26**, 340–349: 1940) find that at the highest range ($p\text{H} = 13$) several changes take place. Initially the chromosomes lose their striations of disks, but retain a clear outline. The chromosomes then show two beaded strings with lamp-brush connexions between the beads. Afterwards, the two strings (chromatids) synapse and then condense.

Finally, the chromosomes lose the lamp-brush structure and may become invisible. The rate of these changes varies with the pH and the later stages may not occur in lower pH ranges. It is suggested that the phenomena are in keeping with the behaviour of a partially folded and partially extended polypeptid chain. The secondary bands are broken by the high pH which corresponds with the iso-electrical part of nucleoprotein. The double chromonema constituting one chromatid only becomes visible when the treatment by alkali concentrates the nucleic acid upon them. Other chromonemata are fully expanded to form the loops and bristles of the lamp-brush appearance. They have been named trophochromatin and are believed to provide reserve material for growth.

Cytogenetics of Maize

THE third chromosome of maize consists of two arms, the long arm being twice as long as the short arm. E. G. Anderson and R. A. Brink (*Genetics*, 25, 299–309; 1940) have summarized their analysis of the genes and translocations of chromosome 3. The order of the genes on this chromosome is cr, d_1, Rg, ts_4, la, na, a; the linkage group consist of 103 units, while cr is positioned towards the short arm. About twenty translocations were found to be distributed from the position of d_1, on the short arm, almost to a, in the distal part of the long arm. The relations of the genes with the translocation and the cytological position of the translocations breaks on the chromosome were determined.

Early Mammals of South America

THE early Tertiary mammals of South America, found in a sequence of five formations between the latest Cretaceous and the latest Oligocene in central Patagonia, were discussed by G. G. Simpson in a contribution to the Eighth American Scientific Congress (May 1940). The earliest faunas contain marsupials, more varied than otherwise known outside Australia, armadillos, ground-sloths and highly varied, archaic, hoofed mammals. During the Oligocene, rodents allied to the tree-porcupines, cavies and chinchillas appeared. The author considers that the hypothesis that these faunas were of Australian origin is poorly supported. He thinks that the peculiarity of the assemblage that occupied South America raises a question that still defies any reasonable answer. W. B. Scott carries on the astonishing story of mammalian evolution from the Miocene to the Pleistocene. The Miocene Santa Cruz beds are mainly stratified ash in which the skeletons of mammals and birds are preserved with exceptional completeness. The fauna is very rich and varied, but is made up almost entirely of groups that are not known in any other part of the world, such as predaceous marsupials, peculiar hoofed animals, the bizarre astrapotheres, ground-sloths, armadillos, and rodents of the porcupine group. In the Pliocene appears the first mammal, a raccoon-like carnivore, of definitely North American origin. The mammals are much larger than their Santa Cruz ancestors, though smaller than their Pampean descendants. Most impressive is the huge marsupial Thylacosmilus, which imitates the sabre-tooth cats in a remarkable way. The Pleistocene fauna of the Argentine Pampean contains a large immigrant element together with a larger one of native origin. The post-Pleistocene extinctions removed the greater part of this assemblage, which included huge sabre-tooth cats, short-faced bears, giant raccoons and chinchillas, exceptionally large hoofed animals and an astonishing variety of edentates which ranged in size from an elephant to a tapir, and included a glyptodont which attained a length of 15 ft. or more.

Earthquakes of South and Central America

B. Gutenberg and C. F. Richter contributed to the Eighth American Scientific Congress, held in May 1940, a paper on the seismic zones of Central and South America. These zones are part of the circum-Pacific belt of activity, which includes a large majority of the shallow shocks of the world, a still larger proportion of those from intermediate depths (60–300 km.), and practically all those from great depths (300–700 km.). Of the branches from the main belt, one diverges in the region of Oaxaca and passes southward by way of the Galapagos Islands and along the Easter Island Rise; the area between the latter and South America is one of principally continental structure. Two other branches follow loops enclosing outlying areas of Pacific structure, one surrounding the Caribbean Sea and the other following the 'Southern Antilles' of Suess. For shallow shocks, the west coast of Mexico is among the most active regions of the world, with frequent great shocks. The activity of Central America is lower, decreasing to a very minor level in eastern Panama. That of the West Indies has often been over-estimated; it is only moderate. In South America, shocks at shallow depth are relatively infrequent, and occur chiefly close to the coast, except in the Mendoza region and in Peru. The high activity of the Andean zone is due mainly to shocks from intermediate depths, with epicentres usually distant from the coast. The great Chilean earthquake of January 1939 had a focal depth of about 70 km. A belt of intermediate shocks crosses central Mexico from west to east and another passes southward through Central America. Shocks from depths greater than 600 km. occur in a few areas far inland in South America. In another paper, presented by N. H. Heck, it is pointed out that of the 95 seismological stations of the Americas, 66 are north of Mexico, 16 are from there to Panama, and only 13 are situated in South America.

Seismicity of the Northern Pacific Coast of U.S.A.

A CRITICAL survey of the earthquakes of the north-west United States has just been made by Perry Byerly (*Bull. Geol. Soc. Amer.*, 51, 255–260; Feb. 1, 1940). The earthquakes concerned had an intensity at the epicentre equivalent to that required to crack walls and cause chimneys to fall. Some of the facts noted by Byerly are that the most seismic regions in the area are the one about San Francisco Bay and the one just off the coast of Humboldt County. These lie in the more persistent fault zones of the coast ranges and their seaward extensions. It is noteworthy that epicentres practically cease at 42° N. and begin again off the coast of Canada. It is suggested that the San Andreas fault zone reaches the border of the continental mass near 42° N., 126° W., and that the stresses leading to earthquakes, which are common on the continent, do not persist in the ocean floor. Another zone of epicentres along the Sierra roughly parallels that just discussed. The only epicentre at sea off the Oregon coast lies roughly on an extension of this zone. The seismic quiet of

Oregon and Washington is marked. The few shocks about Puget Sound were just large enough to come within the classification stated, but were not large shocks. It is noted that it was in Marin County that the greatest fault displacement was observed in 1906. It appears that in this region and possibly in the region of the centre of the Fort Tajon earthquake (1857) farther south there is greater effective friction along the San Andreas Fault which prevents many small shocks and saves the accumulating strain for larger displacements. Perhaps we have here regions of greater pressure transverse to the fault.

Origin of Microseisms

A VERY thorough and important experimental investigation of the nature and origin of microseisms has been carried out at St. Louis, Missouri, by J. Emilio Ramirez (*Bull. Seis. Soc. Amer.*, **30**, Nos. 1 and 2, January and April 1940). The investigation was carried out during July–December 1938, and specially designed electromagnetic seismographs situated at St. Louis University, Washington University and Maryville College had the same timing arrangements by the same clock, being linked together by telephone wires. The results demonstrated beyond doubt that microseismic waves are travelling, and not stationary, waves, the speed of travel being $2\cdot67 \pm 0\cdot03$ km./sec. During the period mentioned, 80 per cent of the waves came from the north-east, none being recorded from south, west or south-west. The period of the waves was from 3·5 to 7·5 sec. and the wave-length was of the order of 14½ km. The waves were found to have many of the characteristics of Rayleigh waves and over a period of more than a year the recordings of microseisms and microbarometric oscillations (recorded by specially designed microbarographs) showed no direct relationship in wave form, group form, period or duration of storms. The source of the microseisms was over the sea, the amplitude of the microseisms depending only on the intensity and widespread character of the deep barometric lows travelling over the ocean. The period of the microseisms appeared to be a function of the distance between the station and the source of microseisms, though no indication of the mechanism by which microseismic storms were caused was obtained, and large microseisms were evident at times when there was no surf near the coasts or winds blowing from land to ocean.

Accretion and Stellar Energy

R. D'E. ATKINSON has attempted to determine the maximum possible rate of accretion of diffuse matter by stars (*Mon. Not. Roy. Astro. Soc.*, **100**, 7; May 1940). Assuming that a product-formula of the type $A = k.a^xb^yc^z$ . . . . is applicable to all stars, the factors which may reasonably be considered are the star's mass, radius, speed through the diffuse matter, density of the diffuse matter, and the constant of gravitation. If, as is possible, it is necessary to consider temperature or the molecular weight of the diffuse matter, the method of investigation pursued in the paper breaks down. Even the five factors referred to constitute a formidable problem, but a safe assumption can be made regarding the density—that it is involved to the power + 1 only. It is found, however, that the problem of the radiation of bright stars cannot be solved by any admissible accretion formula. It seems impossible to find a formula which will give a high enough rate of accretion to account for the energy of the bright stars, using values of the parameters that are permissible. In addition, the rate of accretion cannot even be high enough to produce the dynamical effects considered by Hoyle and Lyttleton, except in the case of very slow moving stars. Even then, it is necessary to extend the time-scale to 10^{10} years or more, and this involves reducing very much the upper limit to the luminosity that can be accounted for by the transmutation of hydrogen, even with the help of accretion. It is possible that the rate of accretion is not given by any simple product-formula. If it is, then some additional factor is relevant, such as the molecular nature or molecular state of the diffuse gas. Finally, it is suggested that the total radiation of the bright stars requires an additional source of energy beyond that provided by the hydrogen they initially possessed and all that they can afterwards collect.

Ionic Character and Dipole Moment

PAULING has regarded the hydrogen halides in the normal states as superpositions of ionic and covalent states, and the fraction of ionic character as given by μ/er, where μ is dipole moment, r is internuclear separation. F. T. Wall (*J. Amer. Chem. Soc.*, **62**, 800; 1940) has developed the theory and shown that the sum of the dipole moments of two states resulting from resonance is the same as the sum of the dipole moments of the original states. By assuming a wave function $\psi = \psi_c + a\psi_i$ for a system resonating between covalent and ionic states, where ψ_c and ψ_i are the purely covalent and ionic functions and a is a parameter, values of $|a|$ are calculated both from dipole moments and from energy values and the two sets of values are found to be in approximate agreement.

Seasonal Variation in the Height of Meteors

R. A. MCINTOSH has examined (*Mon. Not. Roy. Astro. Soc.*, **100**, 7; May 1940) all available published real paths of meteors in an attempt to confirm the seasonal variation found by Öpik. The paper gives a very exhaustive analysis of the matter at McIntosh's disposal, but it is impossible to deal with the various refinements introduced to secure a high degree of accuracy in the results. Some of his conclusions differ considerably from those of Öpik, who used the data provided by the Harvard Observatory Meteor Expedition (*Tercentenary Papers, Harvard Observatory*, **105**, 549; 1937). Öpik found that there was a slightly greater range of heights in shower meteors, that is, meteors associated with the well-established showers on certain dates, some being connected with comets, than with sporadic meteors, but this was not confirmed by McIntosh. There is a decided seasonal variation in the case of sporadic meteors for the three points examined, appearance, mid-point, and disappearance, and the amplitude of the variation is greatest in the lower levels of the atmosphere, maxima and minima occurring earlier than in higher levels. It is obvious from these facts that the cause of the variation lies in the atmosphere. There is a similarly well-marked seasonal variation in the width of the meteor zone. McIntosh points out that Öpik's use of the harmonic mean heights has certain weaknesses and that it is more correct to use the arithmetic means. The author speaks highly of the accuracy of the work of British observers, and in particular of that of the members of the Meteor Section of the British Astronomical Association.

INCREASE IN ULTRA-VIOLET ABSORPTION OF CYTOPLASM AFTER THERAPEUTIC X- AND GAMMA-IRRADIATION

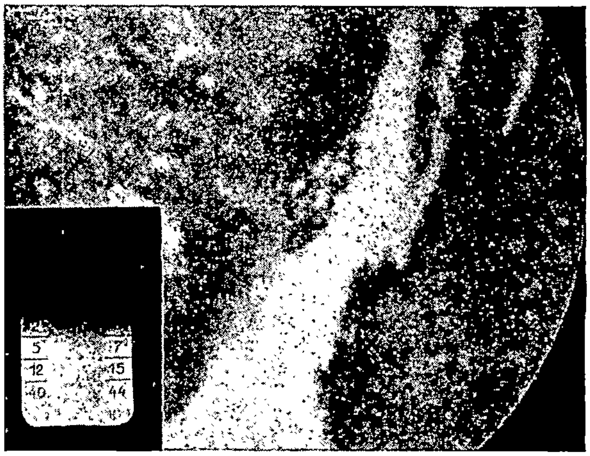
By DR. JOSEPH S. MITCHELL,
DEPARTMENT OF MEDICINE, UNIVERSITY OF CAMBRIDGE

A RELATIONSHIP between the radiosensitivity of tissues and the metabolism of nucleic acid has often been suggested and receives support from certain work, including the possible correlation between the maximum of cellular radio-sensitivity in the premitotic phase[1,2] and the rapid increase in the nucleic acid content of nuclei preceding mitosis[3,4,5].

The aim of the present investigation is to examine the changes in the nucleic acid content, distribution and metabolism resulting from the therapeutic X- and gamma-irradiation of malignant tumours. A technique of ultra-violet microphotography has been developed quantitatively, on the basis of the methods described by Caspersson[3], and applied to biopsy specimens taken from cases during treatment.

The experimental method employs microphotography with light of the wave-length 2537 A., which was selected because of its proximity to the maximum value (2525 ± 10 A.) of the ratio of the absorption coefficients of nucleic acid and of typical proteins in solution. The required monochromatism is attained by employing a mercury-neon discharge tube as light source in conjunction with a chlorine-bromine filter and a photographic plate of correct sensitivity, and has been checked spectrophotographically. The quartz optical system is of the usual type (*cf.* [6,7]) employing a dry objective (6 mm. N.A. 0·70). Sections of control and irradiated tumour are photographed on the same field. From objective measurements of the blackening of the photographic plates under standard conditions, employing a neutral wedge for visible light and radial-sector diaphragms for ultra-violet light, the effective concentration at each point in the sections of nucleic acid or other known absorbing compound can be deduced. For this purpose, a microphotometer of non-recording type has been constructed and also in some cases curves have been obtained by means of a recording microphotometer. An interferometric method has also been developed to measure the small difference in thickness of the sections of control and irradiated tissue.

Measurements have been made on 12 specimens: these comprise 4 squamous cell carcinomata of the lip, 2 squamous cell carcinomata of the fauces, 4 carcinomata of the skin (1 squamous cell, 2 basal cell and one anaplastic carcinoma), 1 squamous cell carcinoma of the cervix uteri, and normal tadpole skin. In all instances the biopsies were taken before and 80 minutes after the end of irradiation; this time was selected to allow the cells caught in division at the time of exposure to complete mitosis. Three cases were treated with X-radiation (effective wave-length ·145 X.U.), 8 with gamma-radiation from radium (applicators) and one with gamma-radiation from radon; the doses used varied from 248 to 4410 r. and the mean dosage rates from 0·317 to 29·7 r./min.



CONTROL IRRADIATED

Fig. 1.

ULTRA-VIOLET MICROPHOTOGRAPHS SHOWING SECTIONS OF CONTROL AND IRRADIATED TUMOUR (CARCINOMA OF THE LIP) ON THE SAME FIELD, TOGETHER WITH A STANDARD NEUTRAL WEDGE (× APPROX. 330).

Control: specimen taken before irradiation.
Irradiated: specimen taken 80 min. after 248 r. in 4·45 hr.

(Treatment with double radium applicator.)

The most striking effect observed was a significant increase in the ultra-violet absorption of the cytoplasm after the X- and gamma-irradiation *in vivo*. This change has been detected after small doses of radiation such as 248, and 388 r. (see Figs. 1 and 2); but it appears probable that the mean dosage rate is a very significant factor in its production. Of the six specimens examined in which the dosage-rates were relatively high (0·91–29·7 r./min.) all gave an increase in cytoplasmic absorption. At low dosage rates (0·32 and 0·53 r./min.) two cases showed no increased absorption while of the 4 cases at intermediate dosage rates (0·53–0·91 r./min.) the two basal cell carcinomata gave a positive effect while the squamous cell carcinomata showed no change.

The increase in cytoplasmic absorption produced by irradiation is of interest in relation to the cytoplasmic absorption recently described[5,8,9] in growing tissues and attributed to pentose nucleotides. The absorbing material appearing after irradiation is not thymonucleic acid itself, as shown by the negative Feulgen reaction, but, at the wave-length 2537 A., corresponds in absorption to that of, for example, a 2 per cent solution of nucleic acid, as in Fig. 1. Thus the magnitude of the observed effect is certainly consistent with the possibility that the increased absorption may be due to purine and pyrimidine

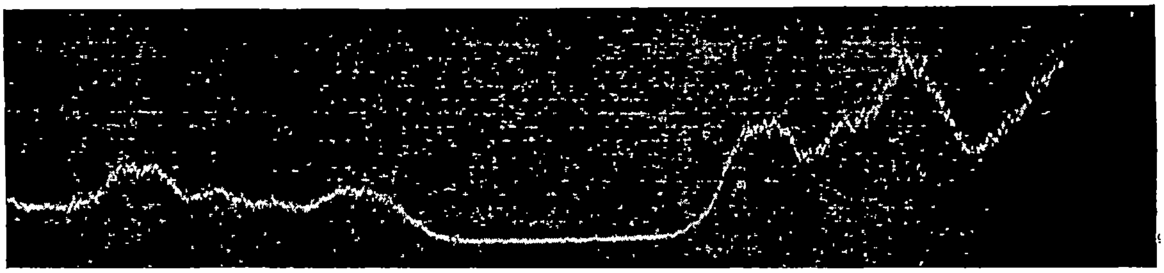


Fig. 2.

MICROPHOTOMETER RECORD OF ANOTHER CASE (CARCINOMA OF THE LIP).
Sections: Control and 80 min. after 388 r. in 6·42 hr.

derivatives. Further, microchemical tests have shown that the increased absorption is accompanied, at least in some cases, by positive pentose reactions in the cytoplasm. This work is in progress and it has been found that the absorbing material can be removed from the cytoplasm in the fixed sections by acid hydrolysis followed by alcohol extraction. Also, *in vitro* experiments have shown that it is unlikely that the observed effect could be due to direct 'photochemical' changes produced in the cytoplasmic proteins by the radiations. At present, little can be said concerning the mechanism of accumulation of the absorbing substances in the cytoplasm as a result of irradiation or of the processes by which they are removed.

On the clinical side, 10 of the cases were treated by myself, and among these there has been no obvious correlation between the response to treatment and the absorption changes described.

I wish to express my grateful acknowledgment to the Medical Research Council and the British Empire Cancer Campaign for financial assistance.

GEOMAGNETIC RESEARCH IN THE AMERICAS*

BY DR. J. A. FLEMING,
DEPARTMENT OF TERRESTRIAL MAGNETISM, CARNEGIE INSTITUTION OF WASHINGTON

THE earth is a great laboratory in which Nature is constantly performing physical experiments. The student of earth physics labours under the disadvantage that systematic and trustworthy data are available for little more than a century. This period is too limited from which to draw many significant conclusions regarding the complex world-wide and cosmical causes and interrelations involved. In the collection of geophysical data, chief attention must be given to geographical and space-distribution and to variability with time characterizing the phenomena concerned. These data must include not only isolated observations on land and sea but also continuous observations at fixed observatories to follow simultaneous variations with time and co-ordination with experiment in the physical laboratories and astrophysical observatories.

The Americas, with their vast areas, their great river-systems, their mountain ranges rising to elevations second only to the Himalayas, and their surrounding Atlantic, Pacific, and Southern Oceans, offer fertile fields for geophysical investigations. Their natural resources are being made available for human use in large degree by the practical applications of geophysics. The magnetic and electric fields of the earth may be considered more in detail as an outstanding example of the opportunities offered such research in the western hemisphere.

Although a few crude determinations of magnetic direction had been made in the Americas toward the end of the seventeenth century, it was not until the historic oceanic magnetic survey during 1698-1700, sponsored by Edmund Halley, that reliable data in the western hemisphere began to be obtained, and then only for the direction of the compass. The magnetic equator—a line connecting all points where a magnetic force is horizontal—crosses Peru and Brazil. One of the agonics—the line along which the compass points true north—passes somewhat west of north from Montevideo through Brazil, western Venezuela, Cuba, and the United States of America. The delineation of the magnetic equator early aroused scientific interest. In 1802, Alexander von Humboldt located it in the Andes near lat. 7° S.

The Governments of the Argentine, Brazil, and the United States of America have been most active in their magnetic surveys. With the formation of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington in 1904 and the inauguration of its world magnetic survey of land and sea in 1905, thanks to the cordial co-operation received from all the American Governments, it was possible for that Department to add many stations to supplement the data already obtained. The distribution of stations of the Carnegie Institution of Washington is densest in those countries not actually executing magnetic surveys. At various times, comparisons of standards with those of other countries have been obtained, and the establishment of absolute magnetic standards of reference has been greatly improved.

---

*Abstract of a paper presented to Section VI (Physical and Chemical Sciences) of the Eighth American Scientific Congress.

Of the 6,000 stations occupied during some two hundred expeditions on land (1904–40) and upward of 4,000 at sea on the *Galilee* (1905–8) and the *Carnegie* (1909–29), at least one third are in the western hemisphere.

The data obtained permit reliable discussions of the distribution of the earth's magnetism and of mysterious variations of its elements from year to year, the so-called magnetic secular variation. These ever-changing lines of magnetic direction and force of the earth, like scientific research, take no account of national boundaries.

Naturally, because of the later opening of new territory in the western hemisphere, Europe at the present time has a great majority of the permanent magnetic observatories. The Americas, however, at the end of the past and during the present century, have established some fifteen permanent observatories well distributed. It would be desirable to have additional observatories at Belem in Brazil and near the southern end of the continent.

Geomagnetic time-changes thus form a main source of information about the physics of the outer layers of the atmosphere, which are subject to distinct cosmical influences on the earth and shield the earth's surface from direct effects. Studies of these outer layers of the atmosphere—the ionosphere—by radio methods supplement magnetic data. Wireless wave-propagation is influenced by the earth's magnetic field, and the location of Huancayo, where the magnetic force is so nearly horizontal, is well suited for experiments on this phenomenon.

The long history of amity and cordial relations between the nations of the western hemisphere supplies a solid foundation upon which in South and North America efforts may be built and co-ordinated for the advancement of earth physics.

PHYSIOLOGY OF PYRIMIDINES*

BY DR. L. R. CERECEDO,
FORDHAM UNIVERSITY

THREE pyrimidines have been found to occur in Nature as constituents of the nucleoproteins, the chief protein material of the cell nucleus. These pyrimidines are: uracil, thymine and cytosine. Recent investigations on the chemical structure of two vitamins, namely, vitamin B_1 and riboflavin, have shown that in these substances we are also dealing with pyrimidine derivatives. In spite of the widespread occurrence of the three pyrimidines present in the nucleic acid molecule, very little is known regarding the function of these substances in the animal economy.

The metabolism of uracil, thymine and cytosine has been studied by several investigators, and it has been found that they are catabolized with the conversion of the nitrogen into urea. The intermediate steps in this conversion, however, remained unknown until they were clarified by studies conducted in our laboratory. As a result of these studies, the following scheme for the intermediary metabolism of uracil was suggested: uracil → isobarbituric acid → isodialuric acid → formyloxaluric acid → oxaluric acid → urea + oxalic acid.

The mechanism suggested by us for the catabolism of uracil has been questioned by Krebs, who studied the action of kidney and liver tissue on uracil, thymine and cytosine. On the basis of his experiments, the details of which have not been reported, Krebs concluded that the pyrimidines were broken down by the kidney, and that the ammonia formed in this process was transformed into urea by the liver.

In view of Krebs's findings, a study of the metabolism of pyrimidines by the tissue slice method has been carried out in our laboratory. The experiments involved a study of the breakdown of various pyrimidines by tissue slices. The extent of the metabolism was determined by means of changes in the urea or ammonia content of the medium in which the tissues were suspended. In a series of experiments the effect of pyrimidines on the oxygen uptake of liver tissue was also determined.

In all the experiments there was no significant increase in either urea or ammonia formation in the presence of the pyrimidines investigated. These results seem to indicate that under the conditions used in our experiments there is no marked metabolism of these substances resulting in the formation of ammonia or urea.

The oxygen uptake of mouse liver tissue in the presence of all the pyrimidines studied, and especially in the presence of cytosine, was significantly higher than that of the controls.

The results of this investigation do not eliminate the possibility of other paths of metabolism involving the formation of substances other than ammonia or urea. The validity of the conclusions drawn from the results obtained is determined by the limitations of the tissue slice method. Since waste products cannot be removed, it is necessary to limit the duration of an experiment to a relatively short period. Consequently, if the rate of metabolism is slow, there may not be a sufficiently large accumulation of end-products to indicate a significant increase. A slow rate of diffusion of the metabolites or end-products would have the same effect. Another limitation of the method is that the cells are removed from their accustomed environment in the animal. Consequently, if the metabolite requires an activator that is not present in the cell itself or in the artificial medium surrounding the cell, metabolism will take place only very slowly and so may escape detection.

THE PHYSICS OF METALS*

CRYSTALLINE bodies owe many of their physical properties to the fact that they are made up of atoms which are more or less rigidly fixed in space so as to form a regular or symmetrical three-dimensional pattern. Metals and alloys consist also of ordered patterns of atoms and are crystalline. The positively charged atomic nuclei may be considered to be embedded in a matrix of surrounding negative electrons. This peculiar structure is responsible for the malleable nature of metals, for their electrical conductivity and for many other characteristic properties. Metal chemistry is thus as distinct a sub-division of chemistry as is organic and inorganic chemistry; each division depending on the particular form of bonding between atomic nuclei.

Those alloys which have valuable mechanical or physical properties, such as excessive hardness or strength, are usually not structurally homogeneous nor in true equilibrium. Consequently, it is necessary to discover not only the relative amounts of the various constituent atoms but also their arrangement in the crystalline pattern. Furthermore it is desirable to determine the particular treatment by which any required combination and distribution can be attained. Empirical metallurgical processes have been developed during the past thirty years with surprising success; but it is only recently that in certain cases the reasons for these processes have been disclosed by X-ray analysis. The ability to 'design' alloys with given properties is the next stage in the progress of metal chemistry. As an example, some advance has been made towards an understanding of the peculiar features of structure which give the new permanent magnet alloys their extraordinary power. This latter property was exhibited by a small magnet which lifted many hundred times its own weight.

The attainment of given mechanical properties may necessitate careful annealing, quenching from critical temperatures, cold working, etc. A series of X-ray analyses throughout successive stages of the process discloses some of the sub-microscopic changes which occur, and leads to a better understanding of the physics of metals and of the facts which determine their properties. Much of the X-ray work now being undertaken is resulting in the compilation of valuable data. The recent work by A. J. Bradley on the ternary systems NiFeAl, CuNiAl, and FeCuAl, discloses some of the underlying physical reasons for the occurrence of certain phases or types of crystalline pattern. In particular, the electron-atom ratios of the alloys appear, as was first pointed out by Hume-Rothery, to be one of the fundamental factors controlling the formation of given phases. On the assumption that iron and nickel have no free electrons, that copper has one and aluminium three, it is possible to predict approximately the phase boundaries in the conventional triangular diagrams which give the composition of these ternary alloys.

MERCHANT SHIPPING IN WAR-TIME

IN *Engineering* of August 9 there is an instructive article on merchant shipping during war-time. To Great Britain at war, the preservation of the sea lanes leading to her ports is of the greatest importance. Canada can produce wheat and other essential materials, the United States can manufacture aeroplanes and military supplies, but facilities have to be available for their transport. The recognition of this need gave rise to grave concern at the relatively heavy losses incurred immediately after the outbreak of hostilities. The prompt institution of the convoy system and the active anti-submarine campaign greatly reduced such losses but as the economist observes, "So successful have they been that the seriousness of the shipping problem has not been fully recognized by the public. . . . Even if there were no submarines and no mines there would be a scarcity of shipping, for the War not only directly absorbs a number of ships in supplying the armed forces overseas, but it also greatly increases the quantities of some bulky raw materials that are required. When, in addition, the annual carrying capacity of shipping is reduced by the delays inevitably associated with the convoy system, the problem is still further increased". It is estimated that the convoy system reduces the effective carrying capacity of the merchant fleet by at least 25 per cent. Not only is the tonnage which enters the ports of Great Britain reduced by the actual destruction of vessels by enemy action, but also many neutral vessels are withdrawn from these routes. The effect of this was shown in the War of 1914–1918. In 1913 if the total of British tonnage with cargoes entering British ports is represented by 68, the foreign tonnage would be represented by 32, whilst in 1917, the corresponding numbers would be 46 and 10 and in 1918, 49 and 8.

Great activity in ship-building followed immediately after 1918. In June 1939 more than three million tons were idle and laid up, the large proportion being of British registry. The fleet of the United States showed the greatest expansion from 5·4 million in July 1914 to 12 million in 1939. The world's tanker tonnage rose eightfold to 11·4 million, held chiefly by Great Britain, the United States and Norway. The efficiency of the mercantile marine was greatly increased, the gain being estimated at about 60 per cent. Sailing vessels have all but disappeared.

The average speed has risen substantially. Oil-burning and motor-vessels have replaced the old coal burners. The British merchant marine, as well as being the world's largest, is one of the most efficient; less than 45 per cent of the ships have a top speed below 12 knots and 24 per cent have a speed in excess of 15 knots. In 1938 Great Britain launched only one million gross tons of new shipping as compared with 1·9 millions in 1913. It is considered probable that the 1940 total will approximate three million tons. For the first time in many years, shipyards in Canada and other parts of the Empire are working at full capacity. This activity will increase the new tonnage available for the replacement of losses and the continued expansion of the services made necessary by the exigencies of the War.

STRUCTURAL HINGES OF REINFORCED CONCRETE

In reinforced-concrete, rigid-frame bridges, particularly in those of long spans, it is desirable, and in many cases necessary, to introduce some form of articulation at the bases of vertical members where high deformation stresses would otherwise occur due to temperature changes and shrinkage. What constitutes a suitable hinge for such a structure can be determined only by laboratory tests in conjunction with field experience, and a paper which has recently been issued (Bulletin No. 322, Engineering Experiment Station, University of Illinois) entitled "An Investigation of Rigid Frame Bridges: Part 3. Tests of Structural Hinges of Reinforced Concrete", by R. W. Kluge, deals with this important aspect of reinforced concrete design.

The purpose of the investigation described was to obtain information relative to the structural behaviour of several types of hinges adaptable to concrete rigid-frame bridges. Besides being sufficiently flexible to permit the required degree of rotation, a properly designed hinge should be capable of withstanding both compressive and shear forces, be economical to construct and easy to maintain, and the seven examples selected for test were such as might be expected to meet these requirements.

The specimens, which included tongue and groove joints, simple pivots, a modified Mesnager hinge and a flexure fulcrum hinge, were, with one exception, made from concrete designed to have a strength of 3,500 lb. per square inch at 28 days and were tested to destruction under vertical loads, oblique loads and rotation and time loads.

While the limited scope of the investigation did not permit of any general conclusions being reached, the results provide a basis for further study. They do, however, give information as to the most suitable designs for a given type of bridge and show that under vertical load the measured strength is in close conformity with the computed strength. In most cases, favourable figures under oblique load were recorded, while, with one exception, they all permitted an angular rotation of 0·004 radian without deterioration even after 10,000 reversals. Pending more detailed investigation, the details supplied in this bulletin are therefore of considerable importance and value to designers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Mechanical Engineering Subjects at the Oxford Schools of Technology, Art and Commerce—The Chief Education Officer, City Education Office, 77 George Street, Oxford (August 28).

Lecturer in Mechanical Engineering—The Principal, County Technical College, Gainsborough, Lincs. (August 29).

Lecturer in Mechanical Engineering—The Principal, County Technical College, Gainsborough, Lincs. (August 29).

Deputy Director of Education—The Director of Education and Chief Executive Officer, Education Offices, 263 High Street, Walthamstow, London, E.17 (August 31).

Professor of Physical Chemistry in the University of the Punjab, Lahore—The Secretary, Universities Bureau, 88a Gower Street, W.C.1 (September 1).

Professor of Anatomy at St. Mary's Hospital Medical School—The Academic Registrar, University of London, Royal Holloway College, Englefield Green, Surrey (September 11).

Assistant Secretary for Higher Education—The Secretary for Education, County Offices, Aylesbury, Bucks. (September 27).

Lecturer with an Honours Degree in either Engineering or Mathematics at the Royal Technical College, Salford—The Acting Director of Education, Education Office, Salford 3.

Lecturers in Chemistry, Physics, Pure and Applied Mathematics, and Engineering Drawing, for Senior Day and Evening Classes, and Lecturers in Building Science S.3, Electrical Technology A.2, Transmission and Distribution A.2, Radio-Communications, and Mechanical Engineering Subjects, for Senior Evening Classes—The Principal, Technical College, Kingston-on-Thames.

Teacher of Mechanical Engineering in the Smethwick Municipal College—The Chief Education Officer, Education Offices, 215 High Street, Smethwick.

Drainage and Irrigation Engineer to the Government of Sierra Leone—The Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/9389).

SOCIAL AND ECONOMIC RECONSTRUCTION

NOTHING could be more marked than the contrast between the aim of the Allies in the present struggle and that at the close of hostilities in 1918. Then everything was directed to the interests of the group, racial or national. Now we fight for the rights of the individual—justice and individual freedom. In both Wars the Allies were constrained to take up arms in resistance to the spirit of aggression, and as it was phrased on that earlier day, "to make the world safe for democracy". In the event, the victory of 1918 became the instrument of group survival. The formula of peace settlement was the application of the principle of self-determination on a national or racial basis and the safeguarding of minorities—not, be it noted, of the interests of the individuals of which those minorities were composed. In the political and economic stresses of post-War years, self-determination, unfortunately, was too readily transmuted into a claim to the right to realize national aspirations, from which in its more extreme form it was but a step to the theory and practice of the totalitarian State and aggressive nationalism. Against such a consequence of the peace settlement to come we must be on our guard. We must not allow our aim to be obscured by the dust of conflict, or refuse to profit by the lessons of the last twenty years.

When the day of settlement comes, it will be no time for the formulation of Utopian schemes of world regeneration. The arduous task of social reconstruction on a world-wide scale will demand the closest scientific study of actual conditions, in which there must be a place for a clear perception of the allowance to be made for the spiritual and emotional factors which have operated and will continue to operate in the social, political and economic spheres of human evolutionary development. In this relation the failure of the last post-War settlement was two-fold. It attempted to restore a pre-War world order which had vanished for ever ; and in so doing it ignored, or failed to appreciate, the significance of the fact that thousands of millions of pounds, the savings of more than a hundred years of prosperity, had been blown into the air. Hence it also failed to foresee the consequences—the immobilization of gold, the paralysis of international exchange of commodities, and as a vain remedial measure, the intensification of economic nationalism—the whole forming a vicious circle, from which in the years preceding the present War it was becoming increasingly apparent that there was no escape short of complete social and economic reconstruction.

While vision failed to discern objectively and on a scientific basis the new set of social and economic conditions imposed by belligerent expenditure in the War of 1914–18, the one great constructive proposal put forward as a palliative for the situation to which the War had given rise, as well as of the conditions in which it arose, the League of Nations, embodied too high an ideal for the stage of social development and consciousness of international responsibility of even the most advanced of the peoples of the world. It attempted to ignore, or to override, differences of culture and cultural history, of temperament and of constitution, social and moral ; but above all it neglected to take into account the group mentality which, as already mentioned, had been fostered and strengthened by the peace settlement—in short, the whole complex of acts and sentiments constituting the rock upon which the League eventually foundered, which may be summed up in the single term 'sovereignty'. Yet, as is so frequently pointed out, it is highly instructive to contrast the political failure of the League with its achievement in the one sphere in which it was supremely successful, namely, that of scientific inquiry in a variety of matters affecting the well-being of mankind on a world-wide scale, in which universal co-operation was possible without the intervention of particularist interests or nationalistic bias.

The contrast in the practical results which emerged in what have been differentiated thus as two spheres of the League's activities points to a difference in concept and outlook which it may seem difficult to resolve. On one side, a rationalistic world in which effort is directed to the objective scientific study of facts and principles with an ultimate view to their utility to mankind without regard to racial, national or other distinction, except in so far as these may in certain eventualities be relevant to the issue; on the other, an arena in which a contest occurs between the interests and aims of discrete groups—interests not necessarily always conflicting, but in so far as they are prepared to co-operate in a common purpose, moved by self-regarding and emotional springs of action rather than a rational and comprehensive conception of a universal aim. Yet it may be that the contrast must not be too deeply stressed. Even in the search for truth of the most detached rationalist, something of passion and emotion must enter to inspire his disinterested devotion to an ideal; while in the give and take of the conflict of groups, emotion alone, even of the most fervent patriotism, has not sufficed to bring about those settlements and compromises in the less spectacular political fields in which the League of Nations has achieved some success, even if it failed on a larger and more conspicuous stage.

This phase of the League's activities is now past history; but its lessons cannot be too deeply pondered with a view to the future. After all, it was a great achievement that the chief powers of the world should have been brought together with the common object of discussion of affairs on a world basis with the view of attaining conditions favourable to the preservation of peace. It was in its mandate policy that the League of Nations perhaps approached most closely to what we should now stress most strongly as the true end of government. It insisted upon the rule of the mandatory Power being framed and directed in the interest of the native population. The well-being of the governed determines the nature and form of government. The State exists for the benefit of the individual and not the individual for the ends and purposes of the State, whether as a unit engaged in a group struggle or as embodied in the persons of a ruling class.

If we accept the fullest development of individuality as the true end of government, not merely individual freedom but also justice must follow as a corollary to ensure the mutual respect of individual rights. That at times the claims of the State must override all individual rights, as in recent legislation in Great Britain, may in the ultimate analysis be regarded as no more than a supreme affirmation of those rights in totality, to which all and every one individually will assent in the interest of all.

How best these interests may be safeguarded in the future, and in what conditions it will be possible for mankind to enter upon the approach to the great social and economic reconstruction which cessation of hostilities will imperatively demand, are problems which still have to be solved. The first essential, it would be generally agreed, must be to bring about such relations between peoples as will ensure the preservation of peace. In the long history of the development of human society, the advancement of the individual and the preservation of the conditions which promote peace both internally and externally in a given group have seen the continual formation of larger and larger groups, held together by emotional, social and economic bonds. Hence the belief that only on some distant day when mankind will assent to a state of world federation will peace be assured. The recent history of the League of Nations would suggest that that day is far distant; but we may perhaps draw inspiration from the remarks made by Mr. Winston Churchill in the House of Commons on August 20 referring to relations between Great Britain and the United States. As he put it, "these two great organizations of the English-speaking democracies . . . will have to be somewhat mixed up together in some of their affairs for mutual and general advantage"; an inevitable process which he compared in homely terms to the mighty waters of the Mississippi "rolling along". This collaboration in the field of defence may yet be the starting-point for a new form of world co-operation in which all men of goodwill, irrespective of creed, race or nationality, may play their parts in the advancement of civilization.

THE ANUAK

The Political System of the Anuak of the Anglo-Egyptian Sudan
By Dr. E. E. Evans-Pritchard. (Monographs on Social Anthropology, No. 4: Published for the London School of Economics and Political Science.) Pp. viii + 164 + 12 plates. (London: Percy Lund, Humphries and Co., Ltd., 1940.) 7*s.* 6*d.*

THIS volume is a noteworthy production from three points of view. In the first place it provides valuable information about a people concerning whom so little was previously recorded that they may be regarded as practically unknown. Secondly, it fills a gap in our knowledge of the great Shilluk-speaking group (though it must be confessed that it suggests a whole series of new questions), while thirdly, from the practical point of view, that is, that from which the work was organized, it has provided the Government with definite information concerning the sociology of a difficult and restless tribe whose administration has hitherto been unsatisfactory.

The Anuak are a Shilluk-speaking tribe of some 30,000–40,000 souls, inhabiting the country of the Baro and Pibor Rivers (themselves affluents of the Sobat) and their tributaries. Part of this territory lies in the Sudan, much of it extends into Abyssinia, and it is this political spread that constituted one of the Government's difficulties, for guns were readily procured in Abyssinia and rebels and trouble-makers could easily cross the border. This they sometimes did, carrying with them the royal insignia, of which we shall presently speak, and thus increased unrest and rendered more troublesome the administration of what is geographically a difficult country.

Linguistically the Anuak are more nearly akin to the Acholi of the south than to the Shilluk. It may be that there are also resemblances in their social organization. On the other hand, the Anuak claim common origin with the Shilluk, and the Anuak kingship certainly resembles that of the Shilluk rather closely, though perhaps not so closely as has hitherto been imagined. Since the author's chief aim was to discover what the Anuak political and royal systems really are, it is only natural that the greater part of this volume is devoted to these particular features. At the same time there is enough information to enable us to appreciate some of the general similarities that the Anuak show to other Nilotic tribes. Indeed there are hints that at one time the Anuak may have more closely resembled other Nilotes than they do at present, when they are predominantly agricultural. Actually considerable difference was found between the eastern and western portions of Anuak territory. In the west it seems that a more primitive condition persists; there is little inter-village organization and the authority of the headmen is for the most part limited to their own village or village group. In the eastern portion of the territory there is a closer relation between villages, and the system of headmanship has given place to a system of nobility and kingship, the latter, be it noted, very much more ritual than executive.

We may best approach the Anuak kingship and its insignia by considering their system of nobility. All nobles, *nyiya* (sing. *nyiye*) are members of a single group, and one member of this group who is in physical possession of certain beads, spears, stools and other objects—the insignia of kingship—is king. It is possible that at one time the insignia passed regularly from father to son, but this has not been the case for several generations. No *nyiye* being sufficiently powerful to retain the insignia for life—should he try he would be killed by a rival—it became more and more the practice for the holder to surrender them to a rival after a year or two, perhaps after some not very determined fighting. A complication—and, from what the reviewer learnt of Anuak affairs before Dr. Evans-Pritchard's investigation, it was this complication that presented the chief difficulty to the Government—was that though every Anuak ruler belongs of necessity to a particular clan with patrilineal descent, he does not become a *nyiye*, eligible for kingship, unless he is invested with the insignia of kingship, nor can the son or descendant of any man not so invested ever become 'king'. Thus every *nyiye* has in fact been king, if only for a few hours. There is no special word for king (unlike the Shilluk), and all nobles display identical signs of rank and are saluted and buried in like manner. When therefore a few years ago, after some rather mixed fighting, the then king withdrew across the Abyssinian frontier taking the insignia with him—at a time before the *nyiya* system was understood by the Government—the possibility of serious political trouble was not far distant.

There is a considerable cult of dead kings at their tombs, and trees that spring up in the immediate neighbourhood are regarded as sacred. Dead kings manifest themselves as snakes, as also do nobles. Sacrifices are made, and the old kings are thought to come from their tombs in their snake form to acquaint themselves with their successors.

In conclusion, it may be emphasized that this volume demonstrates what a capable anthropologist with a general knowledge of the ethnology of an area can learn in a few months by intensive inquiry on particular matters, even when he does not speak the language of the people concerned. During the ten weeks spent on this investigation much time was occupied in actual trekking, 400–500 miles of difficult country being covered on foot, while the average length of stay in each village was about one day. Moreover, the author's serious illness restricted inquiries in the Pibor area. Arabic was the medium of most of the interpretation, though, speaking Nuer, Dr. Evans-Pritchard could sometimes make good use of this language.

C. G. SELIGMAN.

ALPHABETICAL CHEMISTRY

(1) Kingzett's Chemical Encyclopædia

A Digest of Chemistry and its Industrial Applications. Revised and edited by Prof. Ralph K. Strong. Sixth edition. Pp. x + 1088. (London : Baillière, Tindall and Cox, 1940.) 45*s*.

(2) A New Dictionary of Chemistry

Edited by Dr. Stephen Miall. Pp. xv + 575. (London, New York and Toronto : Longmans, Green and Co., Ltd., 1940.) 42*s*. net.

IN the preface to his "Dictionary of Chemistry", published in London in 1795, William Nicholson remarked that "the form of a Dictionary, though, for many years, in high estimation with the world in books on every subject, is confessedly inimical to the natural order of things". Macquer had justified the alphabetical arrangement in his earlier dictionary on the ground that chemistry was then little more than a collection of facts, scarcely entitled to the name of science, or capable either of synthetic or analytic explanation. While pointing out that the progress of chemistry in the interim had been uncommonly rapid, Nicholson urged that "the science of Chemistry possesses little system", in consequence of which "the utility of a dictionary to the Learner will more than compensate for the offence given to the Masters of the Science".

This apology for the chemical dictionary makes strange reading in an age that is able to survey the truly remarkable systemization of chemistry, following the introduction of the atomic theory at the beginning of the nineteenth century and the consequent development within the same century of precise ideas concerning molecular structure and classification of the elements, together with the later ordered expansions into the fields of electronic and sub-atomic chemistry.

Systemization is the keynote of modern chemistry ; and this highly organized branch of science not only tolerates, and indeed demands, the general dictionary serving the needs of the modern analogue of Nicholson's "Learner", but it calls also with equal insistence for specialized dictionaries designed for the successors of his "Masters of the Science". Nor does the chemical specialist confine his attention nowadays to compilations of this second class. Although he makes full use of such specialized dictionaries as Richter's formula-index and Heilbron's name-index of organic compounds, he is equally at home among the pages of Thorpe's "Dictionary of Applied Chemistry" or Ullmann's "Enzyklopädie der technischen Chemie".

Some eighty years ago, Dr. Sheridan Muspratt produced the best-known general chemical dictionary, in the English language, of that age. Of him it was written by "the distinguished phrenological artist", Bally : "You have one of the largest brains in proportion to your size, which constitutes a strong mind . . . great energy—indomitable perseverance ; you possess love of fame or approbation in a very high degree . . . the moral faculties are very good". From this intriguing diagnosis it appears that even in the childhood of modern chemistry the chemical lexicographer had to be a man of parts, animated by powerful incentives. At the present day the domain of chemistry is so vast, and the consequent task of selection has become so onerous, that even a modern Muspratt might well hesitate at the foot of the mountain from which he has to produce his mouse. It is therefore not surprising that the compilation of such works has become increasingly dependent upon the co-ordinated activities of teams of experts, and that some of these alphabetical expositions of chemistry have started as modest dictionaries and grown into encyclopædias in their later editions. The distinction between chemical dictionaries and encyclopædias is not clear, but it would seem to depend mainly upon conciseness.

(1) "Kingzett's Chemical Encyclopædia", by virtue of its wide range and fairly detailed treatment of individual items, is perhaps better

described as an encyclopædia than a dictionary, although either title could be reasonably applied to a work of this scope. "Kingzett" is now something of a household word among chemists. It first appeared in 1919, and the aim of the author, as expressed in his own words, was "to prepare an epitomized digest of chemistry and its industrial applications, in a form which should be useful as a work of reference by all classes of the community". As mentioned by the late Sir Gilbert Morgan in a foreword to the present edition, the production of this work was a labour of love to which Mr. Kingzett devoted most of his leisure towards the close of a successful industrial career. Some time before his death, Mr. Kingzett entrusted to Sir Gilbert Morgan the revision of his annotated fifth edition; but eventually this important duty was transferred to Prof. R. K. Strong, professor of chemistry and chemical engineering at the Rose Polytechnic Institute, Terre Haute, Indiana, who became editor-in-chief of the sixth edition.

Prof. Strong has performed his task admirably. Kingzett's "Encyclopædia" has constantly improved since its original appearance, and in its latest form it contains much new material, including numerous graphs, diagrams, charts, and tabulated data. The treatment of physical chemistry and engineering chemistry has been extended, and the economic aspects of chemistry receive more emphasis than in the earlier editions. That a liberal view of the province of such a work has been adopted is further shown, for example, by the inclusion of a special article of seven pages on bacteria. Copious references to special sources are given at the end of important articles: this is a valuable feature of the work. To choose a few entries at haphazard, here the inquirer will find reliable information on such diverse subjects as chemical plant, colloid chemistry, electricity, heavy hydrogen, gassing, glyptal, nitrogen fixation, paints, petroleum, sherardizing, 'Staybrite', tung oil and wave-lengths.

(2) There is no difficulty in classifying Dr. Miall's new work as a dictionary, rather than an encyclopædia, of chemistry. With the help of numerous experts, whose names are given, he has produced an alphabetical treatment of remarkable conciseness, comprehensiveness and clarity. As a measure of the book's conciseness it may be noted that an average page may contain from about five to fifteen entries. The chemical elements and their important derivatives and minerals, together with a large and representative selection of organic substances, are assigned separate headings. Chemical change and individual chemical reactions of importance are treated from various points of view. Diagrams have been used sparingly, but there are copious structural formulæ and many valuable tabular statements. The humanistic aspect of chemistry finds an expression in brief accounts of noteworthy chemists of these and former days, interspersed in the alphabetical sequence. References to other sources of information are sometimes given in individual articles, besides which there is a list of representative books dealing with the main divisions of chemistry. The volume also contains a convenient table of physical constants of nearly two thousand organic compounds described in the text.

As Dr. Miall recognizes in his introduction, omissions and errors are inevitable in a work of this kind, particularly in a first edition. Up to a point also, the selection or rejection of individual items must be determined by arbitrary decisions. In following out a specific inquiry we found, for example, no entry under the headings of antiseptics, bacteria, disinfectants, germicides, or sterilization; nor could we discover any note on 'Nylon'. The structural formulæ are impressive in their neatness, but we notice that quinquevalent and tervalent carbon atoms—those ineradicable weeds in the garden of organic chemistry—rear their familiar heads in the representations of α-cadinene and phellandral. Menthone is wrongly described as an aldehyde, and it is only partly converted into isomenthone under the conditions mentioned. The odour of piperitone resembles peppermint rather than camphor. Some of the biographies (for example, the first two on p. 320) call for revision.

There is no need to multiply allusions to the fine detail of the work. Viewed as a whole, it forms a really valuable addition to the literature of general chemistry. Dr. Miall and his collaborators have produced a very handy and attractive chemical dictionary, which by reason of its simple and concise style, interesting presentation, and neat format will be welcome to a great variety of users ranging from teachers and students, engineers, pharmacists, medical men, and the intelligent layman in general, to chemical technicians and specialists. It is a work that will inevitably be found in a well-thumbed condition upon the shelves of reference libraries of all kinds.

It may be added that Dr. Miall's expressed intention of enlisting the help of American chemists in bringing out a revised edition of this work at a later date appeals strongly to a reviewer who has held for many years that increasing Anglo-American co-operation in the field of general chemical literature should be a primary aim of all English-speaking chemists.

JOHN READ.

ARCTIC AND ANTARCTIC

(1) Two Men in the Antarctic

An Expedition to Graham Land 1920–1922. By Thomas Wyatt Bagshawe. Pp. xxi + 292 + 33 plates. (Cambridge: At the University Press, 1939.) 15*s.* net.

(2) Greenland Journey

The Story of Wegener's German Expedition to Greenland in 1930–31 as told by Members of the Expedition and the Leader's Diary. Edited by Else Wegener, with the assistance of Dr. Fritz Loewe. Translated from the 7th German edition by Winifred M. Deans. Pp. xx + 295 + 47 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1939.) 12*s.* 6*d.* net.

(3) Arctic and Antarctic

The Technique of Polar Travel. By Colin Bertram. Pp. xii + 125 + 13 plates. (Cambridge: W. Heffer and Sons, Ltd., 1939.) 7*s.* 6*d.* net.

THESE three books together touch most sides of polar interests and in some ways each is complementary to the other two. Two of them are accounts of expeditions, one to the north, with abundant modern equipment, the other to the south with a minimum of outfit and even of preparation. The third volume looks objectively at the whole game and is a discussion of the technique of polar travel. They are all books of interest and value, written by travellers of wide experience.

(1) Mr. Bagshawe with Mr. Lester were two of the four members of a much-noised expedition to Graham Land in 1920, that held out promises of great achievement. But the expedition fell short of all hopes, and when the leader returned with the whaler that carried his men, these two decided to stay. They were not made of the stuff that gives in. In a hut built of a boat and packing cases, with a few stores and much penguin and seal diet, they survived the winter in good health. True, they were in one of the mildest parts of Antarctica, the west of Graham Land, and it was equally true that, through lack of equipment, they attempted no long journeys. Thus they made few discoveries, though their meteorological and biological observations were of value. The chief place, however, that the venture will take in the story of the Antarctic is the proof it affords that men of resource can survive in the Antarctic on little beyond the produce of the sea. It is a spirited, buoyant narrative, written in vivid chapters and well illustrated.

(2) The second volume, which is translated from the German, is by the widow of Dr. Wegener, the well-known geographer who lost his life in the German expedition to the ice sheet of Greenland in 1930–31. It is a composite book, incorporating the narratives of various members of the expedition. It supplements previous volumes on the subject. The expedition was planned with great thoroughness and foresight, and had serious scientific aims. The thickness of the ice sheet was to be measured by sonic soundings; deep shafts were also to be cut for temperature observations, and gravity determinations were to be made at various stations. Lastly, the climate of the interior of Greenland was to be studied with the help of a winter station in the interior at a height of about ten thousand feet. On the west coast on Umanak Fjord and on the east coast on Scoresby Sound there were also to be stations. Much of the work was successfully carried out, but the difficulties were great. The mechanized transport that was to be used to carry the hut and stores to the interior proved unreliable. Moreover, the surface was worse than had been expected, and the Greenlanders did not prove good travellers on the ice-sheet. With great difficulty the central station of Eismitte was founded, 250 miles from the coast, but it was little more than a series of deep holes in the ice. However, two men survived the winter in its chilly depths and did their work. Dr. Wegener, the most experienced member of the party, lost his life in a journey from Eismitte to the coast, and other members suffered severely. But the work was done and the book, apart from its thrills and tragedies, is a record of great achievement and embodies many facts of value. There are good maps and illustrations.

(3) Mr. Bertram's book strikes a new note. With experience in the Arctic on Bear Island, that desolate spot in the Barents Sea, and in East Greenland, he joined Mr. Rymill's three-year expedition to Graham Land. Thus he is fully qualified for his task. The book is not long, but it covers the ground adequately and is written in a fresh and direct style, singularly free from the customary conventions of books of polar travel. Here is the truth as regards not merely equipment, food and transport, but more important still the reaction of the individual to the polar environment. The book is all the more vivid for having been written, at least in part, in sledge camps in Graham Land. Trial and error are at the base of all polar technique, but tradition has tended to clog progress and not enough attention has been paid to the lessons that Eskimo can teach. Science, of

course, has minimized the chance of disease and has done much to improve transport, but perhaps the greatest advances in polar technique in recent years have been due to the extreme youth of many recent polar travellers. In happier days the Arctic at least became almost a holiday ground for the youths of our universities, and they were ready to throw aside tradition and try new methods, often with great success. This is one of the most interesting polar volumes of recent years, and is admirably illustrated by drawings and photographs.

R. N. R. B.

THE THEORY OF GROUP REPRESENTATIONS

The Theory of Group Representations
By Prof. Francis D. Murnaghan. Pp. xi + 369. (Baltimore, Md.: Johns Hopkins Press; London: Oxford University Press, 1938.) 22*s*. 6*d*. net.

FELIX KLEIN'S famous enunciation—"Given a manifold and a group of transformations of the same, to develop the theory of invariants relating to that group"—not only describes the spirit of geometry but also reveals that the concept of a group dominated at least one important branch of mathematics. In the fundamental structure of other branches, however, groups are to be found, and the general concepts developed during the latter half of the last century both by Klein and his student friend, Sophus Lie, were responsible for the far-reaching influence which the relevant theory has had on modern mathematical thought. It is not always easy to discover the first important application of a newly developed theory but it is probable that the formulation of the mechanics of the atom made by Heisenberg in 1926 by the application of the theory of matrices—the invention of Cayley in 1858—is a fair illustration of the excursion of that theory into the practical domain.

In 1926 also, Herman Weyl wove the group theory into the fabric of quantum mechanics. Indeed, the revolution in modern physics may be said to have begun in that year by the work of Heisenberg, Dirac and Weyl. The vast theory of differential equations, and especially the Hamiltonian equations of higher dynamics, became far clearer under the lens of continuous groups, the theory of which was almost exclusively the work of Lie. As Prof. E. T. Bell aptly remarks: "The far-reaching power of the theory of groups resides in its revelation of identity behind apparent dissimilarity. Two theories built on the same group are structurally identical. The more familiar is worked out; the results are then interpreted in terms of the less familiar".

Bearing in mind this brief outline, it is instructive to turn to Prof. Murnaghan's treatise. In the preface of this book the author states that he has "attempted to give a quite elementary and self-contained account of the theory of group representations with special reference to those groups—particularly the symmetric group and the rotation group—which have turned out to be of fundamental significance for quantum mechanics, especially nuclear physics". Special attention has been given to the theory of group integration, as developed by Schur and Weyl; to the theory of two-valued or spin representations; to the symmetric group and the analysis of direct products; to the crystallographic groups, to the Lorentz group and the concept of semi-vectors as developed by Einstein and Mayer.

The text begins with a lucid treatment of the group concept leading to its representation. Matrices are thus introduced and canonical forms discussed. Then follows a general chapter on reducibility in which Schur's lemma on irreducible collections of matrices, the theorems of Burnside, Frobenius-Schur and Auerbach are considered. The Kronecker product and powers form the substance of Chapter iii; the symmetric group and its characters, the alternating group and linear groups occupy Chapters iv–viii, and the remaining five chapters are concerned chiefly with group integration, the orthogonal group, spin representations of the rotation group, the crystallographic and the Lorentz groups.

The mathematical development of the theory has been skilfully carried out with clarity and rigour, whilst the printing—by no means simple—is a model of efficiency and painstaking care. There are no exercises nor applications although the author points out that, with the co-operation of Prof. J. A. Wheeler, a chapter on the actual applications of the theory to the concrete problems of nuclear physics was originally planned for the volume, but, unfortunately, space considerations prevented its inclusion. This is undoubtedly a disadvantage for it would have added greatly to the interest of the student. However, the author has promised to deal with these important applications in a future publication, and this will be a welcome sequel to the present treatise. It may be added that four pages of references to relevant books and papers are given at the end.

F. G. W. Brown.

SCIENTIFIC ORGANIZATION OF WORK

A Chance for Everybody
A Liberal Basis for the Organization of Work. By Hyacinthe Dubreuil. Pp. xvi + 270. (London: Chatto and Windus, 1939.) 7*s.* 6*d.* net.

THE essential idea which M. Dubreuil expounds in this book he has already put before scientific workers in Great Britain in papers presented before the Department of Industrial Co-operation of Section F (Economics and Statistical Science) at meetings of the British Association in 1931 and again in 1934. His advocacy of co-operative contact work by autonomous workmen's teams was further discussed at recent management conferences at Oxford. M. Dubreuil now gives us not merely a fuller exposition of his detailed ideas but also something of the philosophy which has led him to offer this solution to the problem of mechanization, particularly in large organizations.

M. Dubreuil starts by asserting that scientific organization of work will only complete its evolution when it succeeds in bringing into play not only the physical capacities of the worker but also all the intellectual and moral forces that a man can develop when he works in a state of perfect freedom. It is in this sense he speaks of 'chance'—not merely opportunity but scope, the chance to try one's luck, to reap the fruits of the application of one's intelligence to life's infinite possibilities. Only as industrial organization opens before every worker this vista of 'chance' does M. Dubreuil believe it is possible to eliminate the frustration and depression with which mechanization has afflicted many of the workers in modern industry. The real problem is in the transformation of the relations that men maintain among themselves, and not the relations between a man and his tools.

This is the key idea in M. Dubreuil's scheme: it is not enough to improve material conditions by measures of protection and assistance: we must also supply the means by which the workers can attain to the combination of satisfactions that makes life worth living. If undoubtedly education has a part to play here, M. Dubreuil believes that work can and should be organized to permit the expression in it of human personality, and that such expression should not be confined merely to leisure hours.

On this ground alone, M. Dubreuil's plea for the study of the functions and possibilities of the small unit or group deserves attention. To concentrate, as has been the tendency of late, on leisure as providing the sole source of expression of personality or creative capacity for the majority of workers, even if the tendency towards increasing leisure were unchecked, is to doom men to drudgery for a large part of their waking hours. At best it is a defeatist attitude. At the worst it may rob mankind not merely of moral and intellectual satisfaction but even of technical achievements and possibilities of material advance because men are denied the opportunity of giving expression to their innate abilities.

The weakness of other systems, the reason why large organizations fail to achieve the expected results, the failure even of workers' ownership of factories and their control of purchases and sales, M. Dubreuil attributes fundamentally to the payment of wage earners by time and the apparatus of constraint which the clocking-on system involves. The inner urge towards constructive thought and action can only operate when men are assured that the fruit of their ingenuity will be theirs without restriction.

M. Dubreuil does not claim to be the originator of his basic idea of functional autonomy. His debt to J. B. Godin is freely acknowledged. But in his firm rejection of the wage system because it excludes the idea of chance and discourages the worker from putting forth all the effort of which he is capable, he takes Godin's ideas further and enunciates four fundamental rules or principles for the application of his system. These rules or principles are:

(1) Free recruitment of workers by their collective unit, constituted as a co-operative labour group.

(2) Collective undertaking of specified work for a price agreed between the employer and the delegate of the co-operative labour group.

(3) The workers grouped in the collective undertaking themselves choose their leaders and freely organize the execution of the work entrusted to them.

(4) Distribution of the total price of the work among workers according to the method of sharing judged by them to be suitable.

M. Dubreuil believes that such groups organized within a large undertaking by some species of molecular change could revivify them and avert some of the inertia which is liable to overtake them. Not only is each member of the group interested in giving the highest possible value in his own contribution, but he is equally interested in a similar raising of the standard on the part of all the others, and consequently in helping them when the opportunity arises. This form of co-operative group, moreover, avoids the obstacle which severely impedes the promotion of manufacturing co-operative societies. It demands neither the administrative capacity nor the capital which the workers usually lack and requires only their personal capacity for work, knowledge and tradesmen's competence—the only capital they can be expected to put into a common pool.

M. Dubreuil's arguments are supported by interesting examples of collective payment on these lines, and his proposals are not to be lightly dismissed either by those embedded in the traditions of existing organization or by the socialist equalitarian. Whether or not this idea of autonomous groups is capable of general application it is at least highly suggestive, and many scientific workers themselves could corroborate the accuracy of some of M. Dubreuil's arguments and suggestions. At least the idea deserves careful exploration, for we can afford to miss no opportunity of releasing those forces or capacities of the individual which the modern industrial age does so much to atrophy. Scientific workers have their own particular problems on which M. Dubreuil's ideas have their bearing and they may well be grateful to Mr. R. J. Mackay for this admirable translation and the excellent note which he contributes to introduce the volume to a British public.

R. BRIGHTMAN.

DUAL-PURPOSE COWS

Dairy Cattle and Milk Production

By Dr. Clarence H. Eckles. Third edition, revised by Ernest L. Anthony and Prof. Leroy S. Palmer. Pp. xv + 520. (New York: The Macmillan Company, 1939.) 18*s*. net.

THIS is a work of great merit, and can be recommended to all interested in agriculture, both farmer and student, in the United States of America and also in Europe. It has been written in a practical vein, but the fullest use has been made of the findings of the research worker of recent years, and there is the feeling that the latter and the practical agriculturist are in certain respects brought closer together.

The distribution of the material among the thirty-three chapters is good, with the result that a great deal of ground is usefully covered. Chapters iv–x, dealing with the breeds of cattle and to some extent with their classification, are on the whole excellent. The British agricultural student might be forgiven for criticizing some of the material in Chapters ix and x, and it is unfortunate that use is still being made of the term 'dual-purpose' in reference to cattle. It is among the most dangerous of words, particularly when used in conversation with a student. No two breeders ever have the same thing in mind when they use the word. The definition of the term at the beginning of Chapter x appears a little unconvincing to the writers themselves, and is undoubtedly so when read with preceding and following pages.

Under the heading of dairy temperament on pp. 26 and 27, we read "The cow that shows these characteristics to a marked degree—*the ability to fatten naturally towards the end of a milking period* —is said to have a good dairy temperament". If there is one quality that characterizes a Shorthorn more than another it is precisely this quality. Notwithstanding this, we find this breed discussed in Chapter x under 'dual-purpose cattle'.

My chief objection, however, is to the use of the term at all with reference to a breed. There are cows in every breed, including Jersey and Guernsey, with all the defects which are alleged to make up a dual-purpose breed. Fig. 6 on p. 27 illustrates this. Finally, students are always in doubt as to the merits of a cow in late lactation or when dry if she carries a good deal of flesh at that time. Such a cow will in nine cases out of ten be described as a dual-purpose cow, when she is probably a first-class dairy cow.

There are dairy breeds and beef breeds, both of which fit in with specific and often widely differing systems of farming. There are other systems of farming less well adapted to the ideal requirements of these breeds. Any breed farmed under these conditions for a long enough period tends to develop those characteristics which to-day we speak of as dual-purpose.

The use of the word has up to now been badly misunderstood in its application to cattle, and it would be better if it could be abolished. Among breeders of dairy cattle it is all too often a term of abuse, whereas any breed that can from generation to generation stand up to conditions not ideally suited to maximum production is a breed that must play an important part in the agriculture of many parts of the world.

The authors are to be congratulated on a good piece of work.

K. W. D. CAMPBELL.

MATERIALS OF CONSTRUCTION

(1) Materials of Construction

Their Manufacture and Properties. By the late Prof. Adelbert P. Mills. Second, third and fourth editions, edited by Harrison W. Hayward. Fifth edition, rewritten and edited by Prof. Lloyd F. Rader. Pp. xii+564. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1939.) 24*s*. net.

(2) Johnson's Materials of Construction

Rewritten and revised by Prof. M. O. Withey and James Aston. Eighth edition. Pp. xxii+867. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1939.) 36*s*. net.

FOR many years each of these two books has been recognized as a standard work on the subject of the materials used in engineering construction, and these new editions have therefore to be judged not by the criteria applied to new and untried works but in order to see how far they have been brought into line with current knowledge and practice. Though they deal with the same subject, the two books bear the stamp of individuality which may be traced to the impress of the original authors.

(1) In the fifth edition of Prof. Mills's book, his successors have retained his original purpose of providing a text-book covering the manufacture, properties and uses of the more common materials of engineering construction. His plan was to put the information in a concise and thoroughly modern manner, and though intended primarily for use as a text-book of a somewhat elementary character, the treatment was in many respects sufficiently detailed for the book to serve as a work of reference for the practising engineer..

Herein is to be found one reason for the success of this book, for it is essential that every engineering text-book without exception should have this practical orientation. If the subject is not presented with due attention to its applications in the best engineering practice, the book becomes merely a scientific treatise and must fail to find acceptance as an engineering text-book. Thus, properties of materials are not merely exhibited and discussed, but are also related, on one hand to qualities of the raw materials and to the nature of the manufacturing processes and treatments and, on the other hand, to the wide range of possible uses to which they may be put.

This valuable mode of treatment which provides the student and the inexperienced engineer with the means of weighing the pros and cons and of making the right use of new and improved materials, properties and qualities, has been well maintained though the matter has undergone considerable change. The fundamental properties of materials are treated and the methods of testing described in the early part of the book, where also such subjects as slip, progressive fracture under repeated stress, creep and corrosion are discussed.

Besides the usual range of information regarding the properties of metals, stone, concrete, timber, etc., the subjects of metallography and the constitution of metals, now recognized to be of great importance to the engineer, have received greater prominence. Of the more recent materials to come into use, the bitumens, the plastics and the protective coatings have received attention.

(2) The second of these two books has had a much longer history, having been originally published in 1897 and having had a total issue of thirty-seven thousand copies. Its author, Dean J. B. Johnson, clearly realized the importance of accurate knowledge of the mechanical properties of materials in the rational designing of any kind of construction. At that time the investigation of the properties of materials was in its infancy, and this knowledge can only be obtained by patient, expensive and competent research. It is also to be noted that the field of investigation extends, as it were, in three dimensions by the introduction of new materials, by the evolution of new qualities of these and by the extension of the conditions under which they have to serve.

Thus the outlook to-day is much wider than forty years ago, and in order that this book should be as fresh in its attitude and as enlightening in its presentation as it was then, the assistance of experts has been called in so that the information given is as thorough as it is reliable. Taking timber as an example, there is a chapter on the characteristics, properties and uses of wood, in which one section deals with the identification of different kinds. The next chapter treats with deterioration and preservation of timber, while a third gives its mechanical properties, including comparative figures for green and air-seasoned woods. Here also a section gives particulars of the strength of nails, screws and spikes in use with timber.

With similar thoroughness the other materials are presented, the treatment in this volume being in all cases more complete than in the former. Both, however, are excellent within the limits of their scope and may be accepted as fully maintaining the high reputation they have already merited.

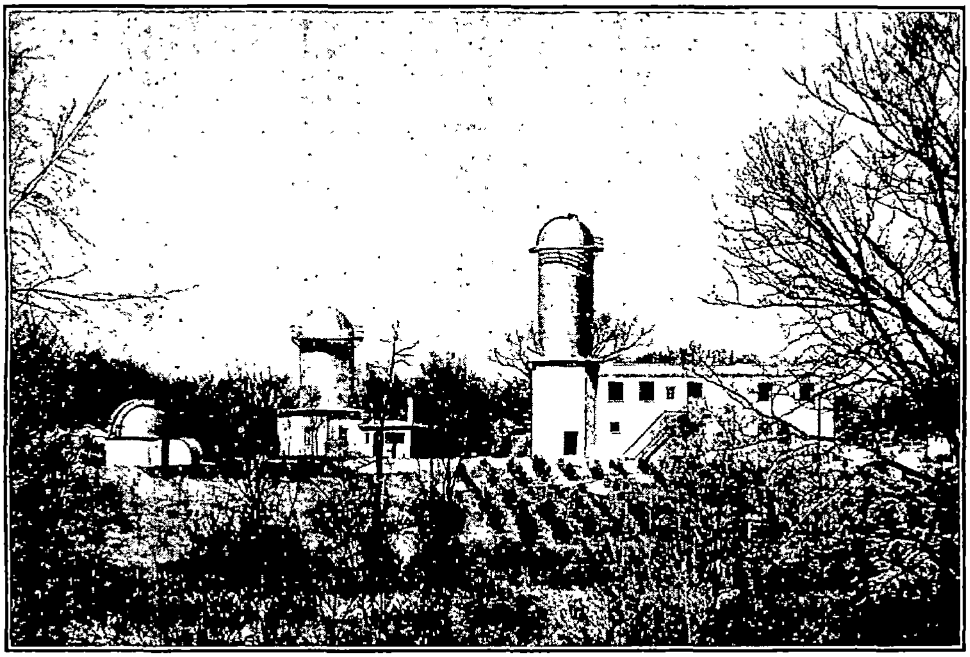
THE McGREGOR BUILDING AND TOWER TELESCOPE OF THE McMATH-HULBERT OBSERVATORY

By Dr. Robert R. McMath

WITH the dedication of the new McGregor Building and Tower Telescope on May 25, 1940, the McMath-Hulbert Observatory of the University of Michigan became perhaps the most complete and powerful installation on earth for the study of the sun. This new addition brings to a total of three the buildings of the Observatory, located at Lake Angelus, Pontiac, Michigan; and besides affording opportunities for studies of the heat, magnetic, and other energy conditions of the solar surface, gives the Observatory much-needed working and office space together with a beautifully equipped modern machine and instrument shop.

The new building is two stories in height, covering an area of 5,600 sq. ft., with the tower forming part of the building at the south. On the first floor is a drafting room, the machine and instrument shop, small film storage, cutting, and dark rooms, and a long laboratory room. The offices are on the second floor, as well as a measuring room, a large dark room with unusually complete equipment for photographic work, a second long laboratory, and the library with a projection booth for showing motion picture films of solar phenomena for study.

To minimize any risk from vibration, the tower and its foundations are of unusually massive construction throughout. Actually, the tower consists of two steel shells, one within the other. The outer tower carries the dome, the floors and other structural elements, and an electrically driven steel elevator which rises in the space between the two towers to carry apparatus to the dome-level. The inner tower carries only the telescopic light-gathering mechanism (cœlostat), which receives the light from the sun and sends it vertically downward in the inner tower and through the various optical parts of the tower telescope proper. Openings in the two steel towers at the levels of the first and second stories make it possible to send the sunlight gathered by the cœlostat mirrors horizontally in to the various pieces of apparatus in either of the two long laboratory and observing rooms which form lateral extensions of the tower. The machinery of the cœlostat in the dome and for other optical parts is not yet in place, but will be made in the instrument shop where any delicate piece of apparatus, large or small, can be quickly constructed.



McMath-Hulbert Observatory from the south-east. The new McGregor Building and 70-ft. lower telescope is at the right.

The promise of these facilities for further progress in the studies of the sun is very great. Previously, the Observatory had been impeded by lack of working space. The McMath-Hulbert Observatory was started as an amateur undertaking in 1929 by Robert R. McMath, the director; Judge Henry S. Hulbert; and the late Francis C. McMath. At that time there was only a 10½-in. reflecting telescope, housed in the smallest and lowest of the present domes. This was presented to the University of Michigan in 1931. Soon after this, a spectroheliokinematograph was attached to this 10½-in. reflector; the first successful motion-picture of a solar prominence, though now regarded as rather crude in comparison with more recent results, was secured in early August 1932, and it was soon evident that many short-lived solar phenomena could be photographed, the existence of which had not been hitherto suspected. As a result, in 1936, the 50-ft. tower telescope was erected exclusively for solar studies. During the past four years, more than 400,000 individual pictures or 'frames' have been taken with this powerful instrument, and have yielded results of great interest and value. But most of the work of design and the study of results had to be carried on in the basement of Dr. McMath's residence. This will be overcome with the greater convenience and efficiency secured through adequate facilities in the new building.

The true purpose of the new unit, however, involves even more technical considerations. The work done in the 50-ft. tower has yielded many films of motions of solar prominences through the development of an ingenious motion picture technique by Dr. McMath. The results have been in two dimensions, and from them a vast amount of evidence has been accumulated as to the character of the motions and changings on the turbulent surface of the sun, but a full study of these motions and of the forces producing them requires much more. During the past year, by means of small shifts in the lines of the spectrum due to velocities in the line of sight, motions in the third direction, that directly toward or away from the earth, have been recorded.

Many questions still remain unanswered, however. It is hoped to determine the temperatures of the streams of flaming materials, speeds of which have been discovered to be so great as ten to fifty or more miles per second. Of even greater importance, more accurate knowledge is sought of the magnetic and electrical conditions accompanying these solar storms, for the manifestations may have a connexion with such familiar phenomena as the aurora, magnetic storms, and interference with radio reception. Other considerations to be studied are the discovery of the heat changes, degree of electrical and magnetic force involved, and the determination as to whether or not the sun's output of ultra-violet light increases at such times. The instruments to be installed in the McGregor Building and the 70-ft. tower telescope will thus be much more in the field of physics than astronomy.

These are all matters relating to the actual nature and cause of solar activity—to the sources of energy and possible terrestrial effects of the movements shown on the solar films. The ways and means of research into these problems are by no means perfectly clear. Unforeseen difficulties may arise. But whatever the results, a powerful instrument is needed for the purpose of studying, through the most advanced techniques of modern physics and astronomy, these energy relations, and searching for the real reasons behind solar phenomena. What discoveries will be made no one knows, but they are sure to be of great scientific interest and value, perhaps even with a more practical terrestrial application.

The McGregor Building and Tower are so named in memory of the late Tracy W. McGregor, founder of the McGregor Fund, which has provided funds for the construction of this powerful research plant and has also made a grant for part of the support of this work during the coming five-year period.

ULTRA-VIOLET AND ELECTRON MICROSCOPY*

By Prof. L. C. Martin,
Imperial College of Science, London

THE compound microscope has now been known to science for about three hundred and fifty years, but the development of the instrument has been curiously spasmodic in spite of its admitted importance. The earliest models were perhaps looked on as little more than toys, and it was not until the publication of Hooke's "Micrographia" that the possibilities were better appreciated. Even so, it seems as if the optical design of the microscope remained for a hundred years largely as Hooke left it.

It became evident during the development of the instrument that the use of single lenses set such limits to the definition as to preclude the effective observation of smaller and smaller objects. The very diminution of the aperture of the objective, though it undoubtedly reduced the aberrations and improved the image to some degree, could not be carried too far without causing a loss of definition due, as we now know, to diffraction of light and of course to loss of illumination. We know nowadays how to build lenses which for all practical purposes are free of chromatic and spherical aberration ; but still the image is not perfect. If the object be a point source of light the image is not a perfect point but is spread into a disk surrounded by faint diffraction rings in accordance with the light-distribution first calculated on the basis of the wave-nature of light by Sir George Airy in 1834.

---

* Substance of a Friday evening discourse delivered at the Royal Institution on May 24.

At this stage it was understood that the only way to diminish the diffraction spreading is to admit the widest possible cone of light from the object into the objective. In order to control the chromatic and spherical aberrations of the objective, a highly complex construction with various kinds of glass is required. The eyepiece now consists of two or more lenses and is free from lateral chromatic aberration. With the most perfect arrangements the limit of close approach for two points in the object, consistent with the possibility of distinguishing their images, is known to be given approximately by :

$$\text{Resolving limit} = \frac{0{\cdot}5\ \lambda}{N \sin U},$$

where λ is the wave-length of light, N is the refractive index of the medium in which the object is situated, and U is the angle between the axis and the most oblique ray from an axial object point which can enter the objective and reach the image.

If the optimum resolution is required, the object is now mounted in some medium with a reasonably high refractive index, such as Canada balsam. The angle U may reach 60° or more and the product $N \sin U$ may be about 1·3 or even higher. The formula was known to be justified in the expectation that violet light ($\lambda = 0{\cdot}45\mu$) will resolve finer structures than red light ($\lambda = 0{\cdot}65\mu$). The precise limits of resolution depend somewhat on the nature of the object and its illumination, for example, whether the object manifests variations of opacity or merely variations of refractive index ; whether bright-field or dark-field illumination is used ; nevertheless, it may be taken that the formula represents fairly well the limit of possibility. What possibilities does it show in the reduction of the resolving limit ?

(1) We may try to increase N by such means as embedding the object in a medium of high refractive index like ethyl cinnamate, and using a very dense flint front lens for the microscope. There are clearly great difficulties in doing this with biological objects as a general practice, although it offers possibilities in metallography.

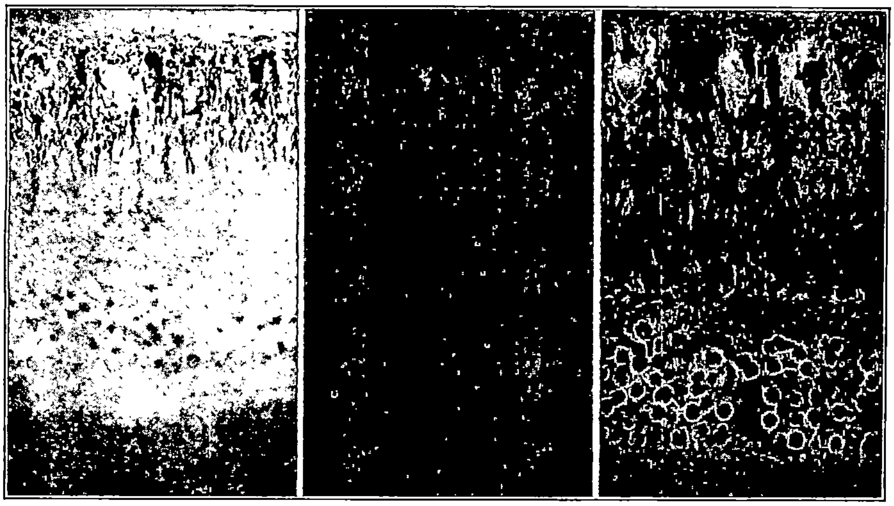
(2) We may try to increase $\sin U$ and take in wider and wider cones of rays. The chief difficulties encountered are concerned with the optical design of the lenses. We cannot make much progress along that road before the losses exceed the gains.

(3) We may diminish λ. The first ultra-violet microscopy of practical import was due to von Rohr and Kohler thirty-five years ago ; they devised a lens (monochromat) which would give an image with light of wave length 2749A. or $0{\cdot}2749\mu$, thus allowing a theoretical resolving limit one half of the amount for visible light. The light was derived from a cadmium spark, the spectrum of which contains a number of bright lines well isolated and homogeneous, so that if the light of a single spectrum line is employed there is no need to make the lens achromatic. As a result the design of the monochromat, though appearing unusual, is such that the aberrations can be kept beautifully low, and if the lens can be properly constructed its performance should be very good indeed. Fused quartz is used as the material.

The method was little applied in practice until the work of Mr. J. E. Barnard in Great Britain directed attention to its potentialities in the field of research on the filterable viruses. Barnard transformed the technique, with the aid of the firm of Messrs. R. & J. Beck, Ltd., so that ultraviolet photomicrography became relatively easy to carry out. Further studies on the technique were carried out by Mr. Johnson and myself at the Imperial College with the view of teaching, and regular instruction has been given ever since 1928.

The use of ultra-violet has many important advantages, however, even if the extreme limit of resolution is not sought after. One is that when using the ultra-violet we can employ a smaller numerical aperture, that is, use a lens taking a narrower cone of light ; then, while retaining equally good definition as with the ordinary lens, we can obtain a somewhat greater depth of focus and get a better picture with a comparatively thick object than with visible light. Again, when 'transparent' objects have to be examined under the microscope, the usual method is to stain them with various dyes which are usually taken up differentially by the various parts of the structure ; but it has been found that differing biological structures vary greatly in their relative opacity to ultra-violet light. Most become opaque at some wave-length, but some will transmit farther into the ultra-violet than others. This can be illustrated by a photograph showing how the structure of a microtome section of the retina of the eye of an owl can be brought out by using various ultra-violet wave-lengths (Fig. 1).

In addition to the low-power monochromat lenses which have been available for some years, achromatic systems made in fused quartz and lithium fluoride have been designed by Mr. Johnson at the Imperial College. These have extraordinarily small variations of focus with wave-length, so that it is possible to focus in visible light and photograph with the ultra-violet; and moreover it is possible to employ a range of wave-lengths for illumination, so that a mercury lamp with suitable filters can be used in place of the usual condensed spark and monochromator system.



$\lambda = 0{\cdot}45\mu$ (violet) × 340

$\lambda = 0{\cdot}362\mu$ (ultra-violet) × 400

$\lambda = 0{\cdot}275\mu$ (ultra-violet) × 400

Fig. 1.

SECTIONS OF OWL RETINA PHOTOGRAPHED IN VISIBLE AND ULTRA-VIOLET LIGHT. (B. K. JOHNSON) 8 MM. MONOCHROMAT. THE SPECIMEN IS UNSTAINED; NOTE THE DIFFERENTIATION OF THE STRUCTURE DUE TO THE EMPLOYMENT OF DIFFERING WAVE-LENGTHS.

We must mention the difficulties preventing the use of shorter and shorter wave-lengths to secure an indefinitely small resolving limit.

With the shorter wave-lengths: (1) both figure and polish of the surfaces must be increasingly perfect; (2) the homogeneity of the optical materials must be increasingly perfect; (3) air does not transmit radiation beyond $0{\cdot}18\mu$, and vacuum or nitrogen-filled instruments become necessary; (4) with still shorter wave-lengths, the usual refracting media become opaque; this requires reflecting instruments, *but* the difficulties in item (1) above then become more severe; errors in reflecting surfaces cause about four times the effect of equal errors in refracting surfaces; (5) for the same numerical aperture, the depth of focus of ultra-violet lenses becomes increasingly small.

The cumulative effect of such difficulties was enough to make it seem probable, a few years ago, that the limits of resolution represented by the ultra-violet immersion monochromats would never be greatly surpassed; we should remain unable to resolve points closer together than about $0{\cdot}1\mu$ or 10^{-5} cm. The discovery of X-ray diffraction by crystals, thirty years ago, mitigated this trouble by providing a means of examining the structure of crystal lattices and quasi-crystalline material. This was supplemented about 1927–28 by the discovery of electron diffraction. It had been known for many years that cathode rays could be deflected by electric and magnetic fields. Already in 1926 it had been shown by Busch that electron streams could be focused by axially symmetrical magnetic or electrostatic fields, much as light is focused by a lens, and the theories of de Broglie had introduced the idea that the motion of the electrons might be associated with a system of waves, which, however, are not to be confused with the electro-magnetic wave motion of light. Prof. G. P. Thomson's diffraction experiments permitted the calculation of the wave-length, which was found to agree with the relation

$$\lambda = 10^{-8}\sqrt{150/V},$$

where V is the potential difference (in volts) causing the electron velocity. Thus if the accelerating potential is 15,000 volts, the wave-length will be 10^{-9} cm. as compared with the $0{\cdot}5\times10^{-4}$ cm. for visible light, and about $0{\cdot}25\times10^{-4}$ cm. for the ultra-violet. At this stage it might have been clear that a powerful new technique of microscopy was possible. It was not, however, until 1932 and onwards that experiments in this direction were begun by Knoll and Ruska in Berlin.

Suppose that an electron is moving in an equipotential enclosure with uniform velocity v_1 and is incident on a bounding surface at an angle i_1. It escapes, through apertures, into a region with its bounding surface parallel to the first, where its velocity is i_2. Since the only acceleration it can experience in passing across the boundary layer is perpendicular to the surface, the component of the velocity parallel to the surface is unchanged, that is :

$$v_1 \sin i_1 = v_2 \sin i_2.$$

If we compare this with the law of refraction of light

$$n_1 \sin i_1 = n_2 \sin i_2,$$

we see at once that there is an analogy between the velocity of the particle and the refractive index (n) of a medium.

Now in traversing an axially symmetrical electrostatic field the electron experiences differences of velocity corresponding to the potential from point to point of its path. Thus it will traverse a path similar to that of a ray of light passing through a medium with axially symmetrical variations of refractive index. The crystalline lens of the human eye is an example of such a case in optics. Though the theory is more complicated than that of ordinary lenses, it can be shown that the image formation and its defects are subject to closely similar laws.

Electron optical focusing systems with electrostatic fields have been largely employed for a study of the thermionic emission of metallic and other surfaces, an image of the cathode being produced on the screen or plate. This is analogous to the microscopy of self-luminous objects. On the other hand, magnetic fields have offered the most direct means for the microscopy of biological specimens.

We copy the early steps in ultra-violet microscopy and use monochromatic radiation ; in this case an electron beam of extremely perfect homogeneity. Even so, transmission through the object and supporting film produces some disturbance of the homogeneity.

Analysis shows that though spherical aberration can be controlled to some degree, we cannot entirely remove it. Consequently we have to copy the earliest step in ordinary microscopy and employ a small stop at the objective, just as was done in Hooke's microscope. We now meet precisely the same difficulties as was the case in those days. We must cut down the aperture to remove the excessive effects of spherical aberration and secure sufficient contrast in the image, but we cannot proceed indefinitely in this because of the loss of intensity and the increasing effects of diffraction.

Suppose that rays passing through the object plane diverge at an angle δ with the axis and pass the objective at an axial distance y. A formula given independently by Parnum and von Ardenne expresses the resolving limit (*R.L.*) in the object plane due to the presence of electrons with a range of velocity potentials dV, considering axial chromatism only :

$$R.L. = y\frac{dV}{V}$$

If therefore $y = 0{\cdot}0025$ cm. and we take a value of dV/V which can be obtained without unduly expensive electrical apparatus (4×10^{-4}), we obtain $R.L. = 10^{-6}$ cm. The approximate focal distance of the objective when working at a high magnification may be about 5 mm. Hence the angle δ will be about 0·005 radians. We have every reason to believe that if the lens system could be free from aberrations, the resolving limit would be represented for some objects at least by the Abbe formula

$$R.L. = \frac{0{\cdot}5\,\lambda}{\delta} \text{ approximately.}$$

Taking the previously calculated value of λ: namely, 10^{-9} cm., we get $R.L. = 10^{-7}$ cm.

On the other hand, a formula has been calculated by Rebsch for the resolving limit set by spherical aberration (when minimized so far as possible). This gives :

$$R.L. = 0{\cdot}1\, f\delta^3$$

Thus $R.L. = 0{\cdot}625 \times 10^{-8}$ cm. in our case.

Considering the three limits above, it would appear that we might improve matters by increasing the homogeneity of the beam and increasing the aperture until the spherical aberration increases to a value comparable with the Abbe limit. There are, however, other considerations which do not appear to have been dealt with in any of the papers hitherto published abroad.

Every optician knows the importance of centring in an optical system ; in a telescope or microscope it is secured by the assembly of lathe-turned and centred parts, but in the electron microscope this cannot be so readily done, because the real symmetry required is that of the magnetic fields. Irregularities of the windings of the coils, variability of the air gaps between coil sheathings and pole pieces, lack of homogeneity of the material of the sheathing and the disturbing effect of the earth's magnetic field ; all these may be present to disturb the perfect symmetry of the arrangement.

If such irregularity is present, there may not be any part of the image which can be said to be truly axial in the optical sense, and consequently all the image points may be subject to lateral chromatism in addition to axial chromatism. The lateral chromatism is likely to produce a one-sided streaking of the image, and represents one of the chief difficulties in working with a cold cathode discharge. Better homogeneity can be secured by a hot cathode and filter circuits to eliminate ripple of voltage. Comparatively recently Bruche and Haagen have used electrostatic focusing, in which the variations of the focusing field potential follow those of the cathode; this should overcome 'chromatic' error.

The chief technical difficulties appear to have been largely overcome by Ruska and his colleagues at the Siemens Works laboratory, although full details of their methods are not yet available.

The objects have to be mounted on collodion films in a vacuum; though the resolving limit is very small, the extremely narrow pencils of rays render the depth of focus fairly large even in comparison with the optical case. This means that the electron optical method is capable of giving a sharp outline picture, even of objects which are of the same order of thickness as ordinary microscopic objects.

What are the chances of lowering the resolving limit drastically enough to render possible a fairly exact measurement of the diameter of the protein molecules?

The above calculations of spherical aberration related to lenses free from axially symmetrical space charges, but control of space charges (for example, we may instance the new technique of phase focusing) is now being better understood. It does not appear to be impossible that spherically corrected electron lenses may ultimately be produced. If so, the history of early microscopy may repeat itself and yet another world be opened up to vision.

THE MEASUREMENT OF ART

BY F. IAN G. RAWLINS,
NATIONAL GALLERY

IT is conceivable that art cannot be measured. Nevertheless, there have been many attempts to do so, and it is not a little remarkable that these efforts are characteristic of the age of the Greek philosophers in much the same way as they are being made now, alongside the rapid progress of theoretical physics.

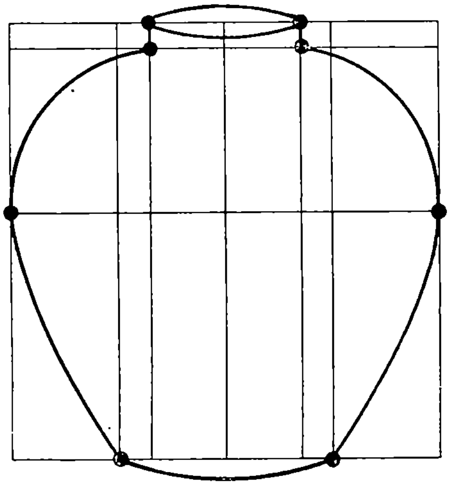
Whatever branch of art is considered, it has become clear that there are at least two categories of æsthetic experience, the formal and the connotative. The first relates to such properties as symmetry, balance, harmony, and so forth, the second to significance or meaning. Thus, a supreme picture will be perfectly composed in design; its function, however, will not be completely fulfilled until its intention (meaning) has exerted its maximum effect. This effect is probably unique. Evidently, the proper enjoyment of art depends upon some degree of formal and connotative training.

Is it feasible now to go farther, and to set up a system of art-metrics, such that personal predilections and judgments may be somewhat disciplined, without doing violence to their essentially intuitive nature? This article will discuss such a possibility in the light of some recent developments. The division of the whole subject into formal and connotative domains will be retained; but it is clear that 'transitional' cases cannot be eliminated, intractable as they may be. It is not difficult to guess which of the two classes of æsthetic experience has been found to be the more amenable to analysis; some writers have almost asserted that the connotative field is utterly unapproachable. This attitude seems doubly unfortunate, for not only does it discourage adventure (which nobody denies is hazardous; but is probably all the more attractive for that reason), but also it denies the possibility of synthesis between the two kinds of experience. The existence of this no-man's-land has been suspected for a long time; to explore it is very tempting.

FORMAL EXPERIENCE

The aim here is to produce an equation, capable of ready numerical solution, which will enable objects within a given category (for example, tiles, vases, decorative designs, melodies, poems) to be arranged in order of æsthetic value. It is important to notice that no attempt is made to compare the relative merits of things in different categories (for example, a vase with a poem). From what has already been said, it will be seen that the basis of such an 'æsthetic formula', as Birkhoff[1] has called it, is largely geometrical, or, rather, the euvalation of a number of severely restricted geometrical properties. These 'elements of order' may not always be positive; ambiguity seems likely to introduce a negative sensation into formal æsthetic experience. An example would be a rectangle which is nearly, but not quite, a square; another would be a grouping of figures just too haphazard to balance, and yet not free enough to be natural.

To express these formal factors, Birkhoff writes $M=O/C$, where M is the æsthetic measure, O is the order (symmetry, harmony), and C is the complexity of the object. This latter quantity is considered to bear a proportional relation to the preliminary effort of attention made by the beholder. Physically O and C are the observables, and from their ratio M is deduced.



T'ANG VASE. REPRODUCED FROM BIRKHOFF'S "AESTHETIC MEASURE", FIG. VIII OF PLATE XVII.

An example will make the method clear. The T'ang vase shown in the accompanying figure in outline is typical; such a two-dimensional representation may be called the 'symbol' of the vase. O is found in the following way: $O=H+V+HV+T$, where H is the number of independent quotients 1 : 1, 2 : 1, taken horizontally on the frame of reference (see figure). V represents the same taken vertically; HV refers to independent relations both horizontal and vertical, and T is the number of tangents defining certain characteristics of the 'symbol'. Further, the complexity C is the number of points, indicated by dots on the outline in the figure, upon which the eye would naturally rest in its attempt to follow the contour. For this vase we find $H=2$, $V=0$, $HV=1$, $T=0$. Therefore, 0 $(=H+V+HV+T)=3$, $C=8$, and hence $M=O/C=\frac{3}{8}=0{\cdot}37$.

The working has been very much abbreviated, but is perhaps sufficient to indicate the method, without embarking upon elaborate detail, irrelevant to the present discussion.

The point is this. The analysis, restricted and arbitrary as it appears, does enable a collection of vases to be arranged in order of (say) decreasing M; moreover, it is found that such a sequence corresponds reasonably with æsthetic judgment. It also seems to take some account of their functional appropriateness, which is interesting, since such a recognition is largely connotative. Modifications of the procedure are obviously needed for other classes of objects, but the general treatment is similar.

CONNOTATIVE EXPERIENCE

To approach this aspect of art measurement is far more difficult, and the results therefore are likely to be less convincing in themselves, and more slender in foundation. The whole outlook is far removed from that of 'safety first'. Nevertheless, an attempt has been made.[2] We recollect that the purpose now is a search for meaning and the possibility of assigning a value to it. This prompts the query: What kind of knowledge (or, perhaps, what science), incorporates an essentially integrative property of form with the basic element of significance? The Gestalt theory of psychology does this, and to such a theory it is natural to turn.

The vital pre-requisite is to obtain a functional relation, in the mathematical sense, between something that can be perceived (otherwise there would be no contact with formal experience) and some elemental property of the object in question, independent of the observer. It is here that the Gestalt concept may be what we need. Consider the doctrine of energy applied to a picture in the making. There is the creative energy of the artist E_c. Then there is the intrinsic energy E_i (at any stage) of the picture which he is painting, and finally there is the free energy E_f of the picture when it is finished, or, for that matter, at any moment of its evolution. Presumably—with certain limitations too complex for discussion here—the total energy of the whole system E is constant and equal to $E_c+E_i+E_f$ algebraically. For a great picture, sublimely conceived, and perfect in finish, E_f is numerically very small (theoretically, perhaps zero): E_c has supposedly decreased, but E_i may be very large. For the moment we are concerned with neither E_c nor with E_i. It is E_f which interests us, for it is a measure of our picture's (connotative) stability, of its power to give lasting satisfaction, in very truth, therefore, of its meaning. We look, then, for the condition E_f=a minimum.

In Gestalt theory, significance is connected with the 'psychological organization' ψ by the law of *prägnanz*, which states that such organization will always be as 'good' (that is, 'symmetrical', 'satisfying', 'stable', and so on) as the prevailing conditions allow. Thus, we are constrained to relate the free energy to the psychological organization, and to write the tentative equation $E_f=F\ (\psi)$.

That value of ψ corresponding to a minimum of E_f gives us the organization associated with connotative stability. This entity ψ clearly has a quasi-geometrical nature, which suggests a parallel with Birkhoff's 'order' O; in addition the function $E_f=F\ (\psi)$ contains implicitly the characteristics of a potential in physics. It will be noticed, moreover, that the observer is not directly concerned in this equation; in a sense, therefore, it is invariant in this respect.

The train of thought just followed has not resulted in establishing a calculus or test of significance in art; perhaps such an outcome is entirely beyond us. It has, however, suggested a connection between the energetics of an object of art (somewhat akin to a closed system in thermodynamics) and a quantity called the organization. From this interdependence some estimate of the effort involved in creation may be obtained, and consequently a glimpse of the cost to be faced in the conveyance of meaning. To repeat: it is not meaning itself which has been measured; it is the price of meaning to which a token value has been given. A sublime work of art, a statue by Michelangelo, for example, possesses vast intrinsic energy; its majesty, however, resides in its (connotative) changelessness—or low free energy—a reminder of the creative energy outpoured in its fashioning.

AN ATTEMPTED SYNTHESIS

We are left with the two relationships, the explicit equation $M=O/C$ (Birkhoff), and the function $E_f=F(\psi)$ (Gestalt). Examination of the complexity C suggests that it has the dimensions $[mt^{-2}]$ which must also be the dimensions of O, since the æsthetic measure M is a numeric. If now E_f is interpreted as a surface density of free energy (rather than free energy itself) this becomes of like dimensions, that is $[mt^{-2}]$. Since M is a measure of merit, it follows qualitatively that, for a given order, æsthetic value increases the lower the free energy density, in harmony with the Gestalt concept, which derives from totally distinct postulates.

Let us return in the end to the contemplation of a supreme work of art. We can, perhaps, determine its æsthetic measure; we can but dimly sense its free energy. Of one thing only can we be sure—of the strife inseparable from its creation.

OBITUARY

Mrs. Tyndall

THE death of Mrs. Tyndall on August 19 removes one of the last links of the Royal Institution with the great era of Victorian science. Louisa Charlotte Hamilton, which was her maiden name, was born on August 3, 1845, and was the eldest of three daughters of Lord Claud Hamilton and Lady Hamilton. Her mother's maiden name was Elizabeth Emma Proby, and her only brother, Douglas James, who assumed the name of Proby in 1904, died in 1931.

Before her marriage, Mrs. Tyndall enjoyed the privilege of meeting in her father's house in London the great men and women—statesmen, writers, and leaders of thought—of a particularly interesting period of British history; with the further experience of residence and travel in Ireland and abroad, where her father held diplomatic appointments. At a time when science and research were studies pursued by relatively few, she became one of an earnest group of women of high social position who followed the lectures on scientific subjects provided by the Royal Institution. It was in the winter of 1860 that she was taken by her mother to Faraday's juvenile lectures at the Institution. Tyndall had then been professor of natural philosophy there since 1853, having been appointed to the post on the recommendation of Faraday, whom he succeeded as superintendent in 1867, but it was not until later that she made his acquaintance when travelling with her father in Switzerland. His tribute to Faraday's genius and loveable nature was paid in his book "Faraday as a Discoverer", first published in 1868—a year after Faraday's death. To the fifth edition, which appeared in 1894, Mrs. Tyndall added a note saying that the preface to it was written a few days before his death.

It was on February 29, 1876, that Miss Hamilton became the wife of Tyndall; and from that time she was, to quote her own words, "his companion in all things". She was a perfect hostess in the busy and intensely interesting years of residence at the Royal Institution, where the superintendent's apartments over the lecture theatre were their home. Here she received a warm welcome in the large circle of Tyndall's friends, which included the Rayleighs, Huxleys, Herschels, Lubbocks, Hookers, Tennysons, Pollocks, Herbert Spencer, and many others. In all Tyndall's investigations and activities, Mrs. Tyndall was his constant companion and an intelligent helper as recorder and amanuensis; in his hard-earned holidays the best of comrades, while ever watchful of his health and untiring in her efforts to find food suited to his weak digestion, which had troubled him from early years.

So early as 1857, Tyndall had paid a first visit to the Swiss Alps with his friend, T. H. Huxley, to make a holiday study of glacier ice. The mountains fascinated him, and from then onwards all his holidays were spent in Switzerland. Soon after their marriage, the Tyndalls built a cottage on Bel Alp, high above Brieg, in the Canton of Valais, and there they afterwards spent their summers. Some years ago, with the ready consent of the local authorities, she erected nearby a simple monument, consisting of a single massive stone, to her husband's memory.

In 1885, the Tyndalls bought about one hundred acres of land on the summit of Hindhead, in Surrey, then a wild heather-clad hilltop, where they built what Tyndall termed a "retreat for my old age". After Tyndall's retirement from the Royal Institution in 1887, most of their time was spent at Hindhead, and it was there that he, whose health had been failing for some years, during which his wife nursed him devotedly, died on December 4, 1893, as the result of an overdose of chloral accidentally administered by her.

The rest of Mrs. Tyndall's life was mainly devoted to the collection of material for Tyndall's biography, which they had jointly planned during his lifetime, and which she intended to write ; but the work was constantly interrupted by the claims of her family and of friends and dependents, and especially of her mother, Lady Claud Hamilton, who died after several years' illness at Hindhead in 1900. Though she lacked the qualifications to deal with Tyndall's scientific work, she contributed an admirable memoir on him to the "Dictionary of National Biography", but owing to her intense admiration for him and devotion to his memory, she was unwilling to entrust the work to anyone else, and various proposals and suggestions as to the choice of a biographer, which might have resulted in the production of the work in her lifetime, came to nothing.

A vast amount of material relating to Tyndall's life and work was collected by Mrs. Tyndall, with the valuable assistance of several friends, among whom Miss M. Dodd (Mrs. Lewin) may be specially mentioned, with the result that when Mrs. Tyndall's health broke down five years ago, the greater part of the preliminary work had been completed. Since then, what was still needed in the way of arrangement and sorting of the material has been put in hand by her nephew, Mr. Granville Proby, and a biography of Tyndall, for the publication of which she provided in her will, is in course of preparation. In addition to Tyndall's scientific papers, the material includes thousands of letters, among them being a large foreign correspondence with Helmholtz, Bunsen, Clausius, Pasteur, and many others.

It is fortunate that, by her devotion to her husband's memory, Mrs. Tyndall was able to preserve so much material relating to his original scientific work, as well as of his advocacy of the use of scientific thought in other fields of inquiry, and his influence in extending general interest in advance in natural knowledge during a very fertile period of development. The biography will be a valuable record of this period and a long-needed memorial to one who did so much to shape it. Two other tributes to Tyndall's memory are the gift by Mrs. Tyndall, some years ago, of a fund of £1,500, administered by the Royal Society for the purpose of encouraging and furthering research in matters relating to mining, and a fine valley at Hindhead, known as Tyndall's Wood, which has become the property of the nation through the National Trust.

WE regret to announce the following deaths :

The Duke of Bedford, K.G., K.B.E., F.R.S., formerly president of the Zoological Society of London, on August 27, aged eighty-two.

Dr. J. Burtt-Davy, formerly University demonstrator in forestry and lecturer in tropical forest botany in the Imperial Forestry Institute, Oxford, on August 20, aged seventy.

Prof. C. F. Jenkin, C.B.E., F.R.S., emeritus professor of engineering science in the University of Oxford, on August 23, aged seventy-four.

Sir Oliver Lodge, F.R.S., on August 22, aged eighty-nine.

NEWS AND VIEWS

Daniel Solander

THE June issue of the *Anglo-Swedish Review* contains an address recently delivered at the annual meeting of the Swedish Academy of Science on Dr. Daniel Charles Solander, F.R.S., the Swedish botanist, in whose honour the Academy's commemorative medal has been issued this year. Solander was born in the small town of Pitêa in the north of Sweden on May 13, 1735. At the age of twenty he entered the University of Uppsala, where he studied medicine and became one of the most gifted pupils of Linnæus, who sent him to London in 1766 to encourage the study of natural history in England. He soon came in contact with Mr. (afterwards Sir) Joseph Banks and was made an assistant in the British Museum Library in 1763. In 1768 he was engaged by Banks to accompany him on Captain Cook's voyage in the *Endeavour* to Tahiti, and in 1772 visited Iceland with Banks. The following year he was appointed keeper of printed books at the British Museum.

Solander was not the author of any independent work, but in 1756 he edited Linnæus's "Elementa Botannica", in 1766 he described the fossils in Brander's "Fossilia Hantoniensia", and in 1786 arranged and described the material in John Ellis's "National History of Zoophytes". In 1764 he was elected F.R.S. and in 1771 was made hon. D.C.L. at Oxford. His name has been commemorated in the genus Solandra and in an island in the Pacific Ocean near the south coast of New Zealand discovered by Captain Cook in 1770. He died at the early age of forty-six of apoplexy on May 16, 1782.

Dr. Félix Gerlier (1840–1914)

DR FÉLIX GERLIER, a distinguished Swiss physician, was born at Ferney-Voltaire in 1840, the son of a local practitioner. He qualified in Paris in

1866 with a thesis on death from cardiac concretions in diphtheria, and then set up in practice in his native town, where he remained until his death on September 6, 1914, except when he served as a medical officer in the French army during the Franco-Prussian War. He was for several years mayor of Ferney, where the high esteem in which he was held led to his being created a knight of the Legion of Honour. Gerlier is best known for his classical description of epidemic paralysing vertigo, to which his name has been given. His first account of the disease was given in 1886 before the Medical Society of Geneva, of which he was a corresponding member, and was published the next year in the *Revue médicale de la Suisse Romande*, his subsequent papers on this subject appearing in this journal in 1888 and 1891 and in the *Archives générales de médecine* in 1899. The disease has a very limited geographical distribution, being found only in the Pays de Gex on the Franco-Swiss frontier and in Japan, where it is called kubisagri and has been studied by Couchoud, who regards it as due to a small coccus. Outbreaks take place in May or June, reach their acme in the summer and come to an end in the autumn. The disease has been found in cats and fowls and appears to be causally connected with close contact with horses and cattle, although they do not contract the disease. The symptoms consist in sudden attacks of vertigo and generalized muscular weakness accompanied by diplopia and amaurosis, and lasting for about ten minutes. Nothing definite is known as to the pathology of the disease, and there is no specific treatment.

Antiquities from the Northumberland Collections

Two important and interesting specimens from the Egyptian and western Arabic collection of antiquities belonging to the Duke of Northumberland recently removed from Alnwick to be placed on loan in the British Museum have been described and figured by Mr. Sidney Smith (*Brit. Museum Quarterly*, 14, 2; 1940). Of these the first is an 'elegant vase' for cosmetics in the shape of a naked slave girl carrying a vase and walking on a pedestal. It was described many years ago by Samuel Birch, keeper of the Department of Egyptian Antiquities in the British Museum, in his catalogue of the collection. He did not, however, as Mr. Smith points out, fully appreciate the singular interest of the figure. Except for a wooden statuette in the Louvre, there is no other example of a similar treatment of movement of the body among such wooden figures. The material has been identified as a boxwood from the Lebanon, and while the Louvre male figure has been assigned to the Eighteenth Dynasty from its resemblance to Syrian figures depicted in the tombs, the figure of the girl is not likely to belong to the early part of the dynasty but is assigned to the reign of either Amenhotep III or Tutankhamen.

The second exhibit described is a cylinder seal of hematite of a shape common in the fifteenth century B.C. and later. Its singular importance and unique character lie in the fact the men and bird depicted on it lie outside the known categories of themes on cylinder seals, yet the seal itself and some elements are normal in Syria about the middle of the second millennium. The men wear light waist-belts and a short kilt flounced, which resembles, though it is not identical with, the Cretan wear for athletes. Mr. Smith suggests that it is not a sufficient explanation of the seal to say that it shows Cretan influence, but that it looks as if a Babylonian seal-cutter was actually depicting men in Syria who wore something like Cretan dress, and copied for this purpose such figures as the running men from foreign art. If this be accepted, this seal and the Egyptian figures throw an interesting sidelight on the spread and distribution of artistic activities and motifs in the world of the ancient East in the second millennium B.C.

The Royal Asiatic Society of Bengal

A RECENT reorganization in the administration and installation of the Royal Asiatic Society of Bengal, which is set out in detail in the recently issued annual report (Year Book for 1939, 6; 1940) has already borne fruit, more especially in a speeding-up of publications which had been allowed to fall in arrear. It is possibly to be attributed to the same quickened interest in the work of the Society that the exhibits shown at its annual meeting on February 5, 1940, attracted exceptional attention, notably in anthropology and archæology, subjects upon which as studied in India criticism has recently been directed with no little vigour from more quarters than one. Of the ethnographical exhibits the most striking was a small collection of the wooden effigies erected in memory of the dead by the Red Kaffirs of the Hindu Kush. These effigies came from the village of Rambur and were collected by members of the Zoological Survey of India in 1929. One represented a man riding a horse and the other a woman wearing the characteristic horned head-dress of the Red Kaffir women. It may be of interest to note that it has been suggested that these figures may have some relationship to certain of the well-known Easter Island figures, of which the origin and purpose have been the subject of much discussion.

Another exhibit of considerable interest was a collection of human skeletal remains recently excavated by the Archæological Department of Gwalior State on a Mauryan site at Kumhar Tekri near Ujjain. With the exception of those found by Sir John Marshall at Taxilla, these are the only human skeletal remains of the Historical Period, which have as yet been brought to light by archæological excavation. It is noteworthy that the great development of the posterior parts of the skull characteristic of the big-brained races of the chalcolithic Indus Valley civilization is not found in the skulls of the Historic Period.

New Regulations for Pharmaceutical Examinations

NEW regulations governing the conditions prerequisite to pharmaceutical qualifications have been made by the Council of the Pharmaceutical Society. The work of revision began in 1936 and the sub-committee which was appointed for the purpose was assisted in its deliberations by representatives of the

Ministry of Health and the Department of Health for Scotland and by the external registrar of the University of London. The revised regulations, which affect both the Society's examinations and the curriculum of study, will come into operation in October, subject to the approval of the Privy Council. The syllabuses for the Preliminary Scientific Examination, to be known in future as the 'Intermediate Examination', have been simplified to some extent and the changes are in favour of candidates rather than otherwise; for example, organic chemistry will not be taken at this stage in future. The physiology of heterotrophic plants has been deleted from the botany syllabus and saprophytism and parasitism have been added. The wording of the zoology syllabus has been modified with the object of limiting the knowledge which the candidate should possess of histology and otherwise of indicating that attention should be directed mainly to types and not to groups to which the types belong. More important, however, is the provision that the Council of the Pharmaceutical Society may require that the Intermediate Examination shall be passed before the student commences his practical training in a pharmacy or a hospital; this provision is wisely conceived, for the present high percentage of failures clearly suggests that many candidates would be well advised to choose some career other than pharmacy.

With regard to the Qualifying Examination, there has been some unloading of the syllabuses, but this does not appear to reduce the general standard of requirements. In pharmaceutical chemistry the candidate's knowledge of tests for purity and of chemical assays will in future be limited to those of the British Pharmacopœia and, in pharmaceutics, the reference in the syllabus to the biological standards of galenical preparations has been deleted, as the principles underlying these subjects are more appropriately treated in physiology and pharmaceutical chemistry respectively. The changes affecting the Pharmaceutical Chemist's Examination include, in the pharmaceutical chemistry syllabus, the substitution of "adrenaline, thyroxine, vitamins A, B_1 and B_2, C and D" for the crystallizable hormones and vitamins and, in the pharmaceutics syllabus, the addition of the factors involved in transferring small-scale pharmaceutical operations to a large scale. The preparation of bacterial vaccines has been deleted, and disinfectants and the factors governing their efficiency have been added to the syllabus. Another addition is a knowledge of the physiological properties of vitamins. In the requirements for this higher examination, the object of the changes would appear to be directed to an adjustment to more recent developments in sciences allied to pharmacy.

British Birds in 1939

A NUMBER of local societies have recently issued their field records of bird-life in 1939. The London Natural History Society's Bird Report for 1939, issued separately from the *London Naturalist* for the fourth year, covers bird-life within twenty miles of St. Paul's Cathedral and notes more than 160 different species, including such uncommon visitors as the firecrest, great grey shrike, purple sandpiper and Iceland gull, a summary of the arrival dates of migrants for eight years and special accounts of the status of the goldfinch, stock-dove, sandpiper and redshank. The Merseyside Naturalists' Association's 1939 notes from Liverpool (*Ibis*, July) add the Kentish plover to the Lancashire list and the roseate tern to the Cheshire list, in addition to noting such uncommon visitors as the red-necked grebe, black redstart, velvet scoter and a mid-winter record of the little stint, as well as extensions of the nesting range of tufted duck, pochard and herring-gull.

In the home counties, the Oxford Ornithological Society notes the blue-headed wagtail at Slough Sewage Farm, Bucks, in May, June and July, as well as visits of grey plover, turnstone and knot, while in East Anglia, the Norfolk and Norwich Naturalists' Society Bird Report mentions two pairs of marsh-harriers at Hickling and Horsey but only one nest known to rear young, no Montagu's harriers and only about four pairs of bearded tits, a whiskered tern at Hitchling in June and a sight record of the Mediterranean Black Headed Gull in October. A pair of roseate terns nested at Blakeney and dunlin again at Clay, but the latter apparently not rearing young. The Cambridge Bird Club notes bittern, Montagu's harriers and black-necked grebes on Burwell Fen, but not nesting, nor was the black redstart again found nesting in its 1938 haunt. The Yorkshire Naturalists' Union report (*Naturalist*, 1940, pp. 7–18) notes the siskin nesting at Goathland, pintail at Skipworth, and the crossbill at Thornton Dale; goshawk, water-pipit, an immature white-tailed eagle, ospreys and red-legged partridge were uncommon records. The nesting of the arctic tern at Spurn is believed to be a county record.

Public Health Progress in India

THE July issue of the *Asiatic Review* contains an interesting article by Sir Alexander Russell, formerly medical officer of health and professor of hygiene and bacteriology at Madras, on public health progress in India during the last forty years. Since 1911, research work under the auspices of the Indian Research Fund Association has been chiefly connected with India's public health problems and considerable achievements have been recorded, especially as regards plague, cholera, malaria, kala-azar and nutrition, while investigations on the indigenous drugs of India have done much to determine their therapeutic action. The Research Association has also supplied means for the training in research of a large number of Indian graduates of science and medicine. An All-India League was formed in 1921 to promote maternity and child-welfare throughout the country. In 1930 it became the Maternity and Child Welfare Bureau, and now in most provinces the work is carried on either through the official health departments or by voluntary organizations.

The Institute of Hygiene and Public Health provides a course of instruction and a diploma in maternity and child-welfare, while half a dozen small provincial schools serve for the education of health visitors. Since 1929, considerable advance has been made in a campaign against tuberculosis. As regards leprosy, for many years the work was confined to the provision of a number of asylums for lepers, but about fifteen years ago scientific research showed that early cases were amenable to treatment, and in 1934 the British Empire Leprosy Relief Association was founded. In the following year an Indian Council for the Association was inaugurated, and research work was intensified, especially by the Calcutta School of Tropical Medicine.

Disease Among Natives of Alaska

IN a paper read before the Section on Medical History of the College of Physicians of Philadelphia (*Trans. and Stud. Coll. Phys. Philadelphia*, 4, Ser. 8, 27 ; 1940) Dr. Joseph D. Aronson, associate professor of bacteriology in the University of Pennsylvania, remarks that though little is known of the occurrence of disease among the natives of Alaska prior to its discovery by the Russian explorer Khirikoff in 1741, the early reports and records indicate that diseases due to food deficiencies existed and that smallpox, syphilis and tuberculosis were unknown and were probably introduced by the white man. Smallpox, which was probably introduced by the Spaniards, caused more suffering and loss of life than any of the other diseases. The mortality was particularly high among adults and considerably less among children. It soon became clear that in parts where vaccination was employed the disease was brought under control and the mortality fell to 10 per cent or less, whereas in areas where the natives refused to be vaccinated the mortality ranged from 40 to 60 per cent. Syphilis was brought into the country by hunters, traders, and especially sailors, and became widespread. There is no record of tuberculosis either in its pulmonary or extrapulmonary form such as lupus or involvement of the bones or joints, until 1770 or twenty-nine years after the discovery of Alaska. Afterwards it spread rapidly, though it did not reach the epidemic proportions of smallpox.

The Illegitimate Child

IN a review of this subject in the July issue of the *Quarterly Review*, Mr. Claud Mullins, the well-known Metropolitan police magistrate, remarks that illegitimacy is not only a problem in itself but is also a big contributing factor in prostitution, abortion and crime. He points out that the absence of a father from the beginning of the life of the illegitimate child must have a big effect, as it is the father's function to implant in the child impulses which produce law-abiding citizens. Only too frequently the illegitimate child is a rebel not only against the conventions of society but also against criminal laws. Sometimes the dangers of illegitimacy are minimized by the child's early adoption into a normal and healthy home, but most psychologists agree that even with adoption there may be a trauma in the child's unconscious, and this trauma may result in a later hostility to society. Mr. Mullins suggests that there should be a new bastardy law in which the interests of the child should be uppermost, and that regular maintenance should permit decent arrangements to be made for its upbringing and education. In conclusion he recommends the substitution of the words "natural child" for "bastard", and "child maintenance" or "child paternity proceedings" for "bastardy proceedings".

Treatment of Juvenile Delinquents

IN his inaugural thesis (*Thèse de Paris*, No. 1105 ; 1939), Dr. H. Pitoux, who records five illustrative cases, states that of 98 inmates of the Fresnes prison under thirty years of age, 61 had committed their first offence before the age of twenty-one. He recommends that in order to enable a young offender to play a respectable part in society he should undergo a medico-psychological examination, and a careful inquiry be made into his previous social environment. He should then be classified and sent to a centre suitable for his psychical and occupational level. Institutions with a staff specially trained to give the young offender an intellectual, moral and occupational education are needed to enable him to return to society. At the present time only the first part of this programme, namely, the scientific and medico-psychological, has been realized in France, but as regards education much still remains to be done.

Bibliographical and Intelligence Services

THE *Proceedings of the British Society for International Bibliography*, 1, Part 1–3 (1939) include a paper by J. E. Wright on the special library and information bureau established in connexion with the Post Office Engineering Research Station at Dollis Hill ; special reference is made to the use of the universal decimal system of classification in the indexing of literature and information relevant to the work of the Department. Dr. S. C. Bradford contributes a note on the co-ordination of documentation, in which the limitations of abstracting periodicals are indicated, and the lack of co-ordination between the abstracting services leading to incompleteness and inconvenience is criticized. Dr. Bradford again argues that abstracting should be organized from the point of view of science as a whole. The information service of the Imperial Bureau of Horticulture and Plantation Crops is described by D. Akenhead. In addition to *Horticultural Abstracts*, the Bureau has issued twelve technical communications and five occasional papers, one of the latter being an annotated bibliography on the biter pit of apples, and another the translation of conclusions reached by a Russian author on the manuring of fruit trees. Primarily, the information service is for research workers in the Empire, but inquiries from private individuals or from foreign research workers are often handled.

The organization of an industrial intelligence service in relation to documentation is discussed by S. G. Barker, who argues that industry requires a co-ordinating agency for the dissemination of information regarding current work, both published and unpublished. It also requires, he considers, historical bibliographies of failures and successes and historical records leading up to and subsequent to them, as well as an intelligent observation of potentialities in regard to the future. These must be expressed to the business man and technologist in brief terse language, so that on straightforward reading he will readily grasp the essentials and be able to indicate to his subordinates and others what he requires in regard to detail. To do this effectively, co-operation, co-ordination and collaboration with other industrial information sources are essential, and this is the organization we seek.

Books to Read at College

THE Trinity College Bulletin, edited by Prof. H. T. Costello, which comes to us from Hartford, Connecticut, supplies a "List of Books for a College Student's Reading". This, first published in 1925, has now reached a third, revised edition, and deserves to be popular. The aim of the pamphlet is "to bring the best students and the best books together", helping them to avoid waste of time on inferior stuff. This is an excellent idea in view of the present over-crowded jungle of literature, the reduction of which by the stress of the War will, we hope, be permanent. The general reading course before us is well arranged. The List is divided into ten sections, and students are expected to read and write on something in eight of them. "Reading in the greater classics is likely to get special grade credit." This is as it should be. Early specialization pays to-day and interferes with that versatility which belongs to a liberal education. No censorship of ideas is attempted in the lists, and "books that may shock or annoy" are included. The short descriptions added to each item are expert and helpful.

Meteorites in the Indian Museum

A CATALOGUE of meteorites, with special reference to Indian falls and finds and to specimens in the Indian Museum, Calcutta, has been compiled by A. L. Coulson and published as Memoir 75 of the Geological Survey of India, 1940. An order of the Government of India lays down that all meteorites falling in British India are the property of the Government of India and as such should normally find a place in the Indian Museum under the care of the Geological Survey of India. Every effort is made by the Survey to obtain new falls, and these are carefully studied and the results published in the Records of the Survey.

The first catalogue of the collection was prepared by Thomas Oldham in 1864 and gave particulars of 21 stones and 26 irons. By 1914, when Coggin Brown's catalogue (1916) was compiled, the collection had grown to a total of 379, though some of the specimens included in this total have since been found to be identical, due to better knowledge of the various synonyms that have been used in the past. Recently there has been active exchange of meteorites with various British and foreign institutions and on August 1, 1939, the collection included 149 irons and 319 stones, a total of 468 falls and finds. The present catalogue deals primarily with Indian falls and finds, but also attempts to include all meteorites, whatever their locality. References to the most important literature dealing with Indian meteorites and a short résumé of the circumstances of fall or find has been given in every case. Other chapters deal with classification, dates of fall or find and geographical distribution.

A New Direction Indicator for an Aeroplane

ACCORDING to Science Service, Dr. David Luck has described before the U.S. Institute of Radio Engineers a new form of radio beacon for aeroplanes which has been developed after four years research under his supervision at the laboratory at Central Airport, Camden, N.J. It is called the omnidirectional radio-range beacon, and operates with ultra-high-frequency oscillations to reduce the effect of atmospherics to a minimum. Radio-beacons have been in use for several years, but they serve only to confine the pilot to a definite course. Some air lines have used in addition direction finders to show the direction of the transmitting station from an aeroplane, but these are not satisfactory when using ultra-high-frequencies owing to atmospherics.

Dr. Luck described the operation of the new device as follows. When the pilot has to fly around a portion of his course affected by bad weather, he can always 'see' the direction of the radio-station at a glance. If he wants to fly straight into or out from the beacon, he has only to hold the mark steady, at that course, against a scale on the instrument face. The operation of this indicator may be compared to that of a lighthouse sending out two kinds of light, one a beam which sweeps around steadily and the other a flash sent out in all directions the moment the beam points north. The interval is timed from the flash until the beam sweeps over the observer, and then the required direction from the lighthouse is found. In the new radio device, the radio-lighthouse is on the ground and the indicating instrument on the plane automatically times the flash and beam. All this is done electrically, and the lighthouse beam sweeps round sixty times each second.

Recent Advances in Electroplating

ACCORDING to the *Electrical Times* of August 15, the electroplating of chromium is finding a wide application for purposes other than superficial polish and protection. Recently a German technical paper published an account of the utilization of chromium plating for use with steel cutting tools and bearings. A cheaper grade of steel or even common iron may be employed. The working edge is then plated with chromium, which gives it a hardness comparable to that of diamond. The cutting edge may then be ground, for the chromium may be applied in any thickness, and the tool has all the best features of the hardest and most expensive high-grade steel, its life is multiplied by two or even ten, it wears away far more slowly, and will go through most hard metals as if they were cheese. Bearing journals left rather too small as turned out by the lathe may be thickly coated and then turned up to the increased diameter required, thus also obtaining a skin which lasts a very long time. Worn-down tools, bearings, bushes, gauges, valves, and drills can be rendered better than they were when new.

Similar researches have been made with regard to nickel. All buffing and polishing can now be avoided by using a brightening agent in the electrolyte for plating with this metal. The surface can be taken straight out of the bath directly with all the lustre obtainable by polishing, buffing and tumbling. As these processes involve more work than the electroplating itself, the great advantages of the new method are obvious. Other metals, including chromium, are now the subject of research, and it appears more than probable that a high polish in chromium will shortly be obtainable in the same way. Zinc, for example, is already being successfully applied with a high polish on emerging from the bath.

Verifying Telephone Subscribers' Numbers

To avoid the incorrect recording of callers' numbers in a trunk exchange associated with an automatic telephone area, various expedients have been adopted, including the reversion of a certain percentage of originating calls to the use of an audible tone. The supersonic signal method is described in a paper by W. K. Brasher and B. P. Moss (*J. Inst. Elect. Eng.*, July). It was evolved for Palestine, a country in which the use of a number of languages made the problem more acute. It is usual to check a certain number of demand calls either by establishing a second connexion to the subscriber's line, independent of the first, or by 'reverting' the call, that is, recording the particulars of the required number and informing the caller that he will be rung. Both methods lead to delays. Messrs. Brasher and Moss give a full description with diagrams of the method, which is being evolved in Palestine and is now being installed. Demand positions are served by a 20 kc./sec. oscillator, the output of which can be connected to the operator's telephone circuit of each position. When the demand operator has received the particulars of the wanted and calling subscribers, she passes the call to the distant exchange and moves a dialling plug suitably. The basic principle of the use of a supersonic signal in an automatic telephone exchange has been proved by test to be a practical scheme, no disturbing effect on other circuits having been noticed in a 5,000-line exchange.

The Night Sky in September

THE moon is new on September 2, whilst full moon (the harvest moon) occurs on September 16. On September 20 at 21h. and 23h. U.T. respectively, the moon is in conjunction with Saturn and with Jupiter. Saturn, to which the moon makes the closer approach, may be rather overpowered by the moon's glare. On September 28, a lunar conjunction occurs with Venus. On September 22, an occultation (reappearance) of the 1st magnitude star α Tauri (Aldebaran) may be observed at the moon's dark limb. At Greenwich the reappearance of Aldebaran, then only 9° above the horizon, is due at about 22h. 3m.; at Edinburgh, where the altitude is more favourable, the time is 22h. 16m., at position angle 215° from the moon's north point. Jupiter and Saturn continue this month as a notable pair of bright planets to be seen throughout the night. On September 16, Saturn souths at 3h. 11m. and Jupiter at 3h. 14m. (add 1 hour to obtain Summer Time). Close groupings of Jupiter's four inner satellites may be seen at 1h. on September 8, 9, 16, 18, 25 and 26. Venus, unmistakable in its brilliancy, also continues as the bright and morning star rising between 1h. 12m. (September 1) to 1h. 50m. (September 30). On the former date, Venus is about midway between Procyon and Castor and Pollux and by the end of the month has moved to a position preceding Regulus. The darkening evenings of September (the autumnal equinox is on September 23) gives unrivalled aspects, when the moon is absent, of the Milky Way near the meridian. The main features of this half of the great stellar structure are easily recognized—the great rift or bifurcation commencing in Cygnus and extending along the galactic equator: the brighter eastern stream with its various star clouds passing southwards through Aquila, Scutum, Sagittarius to Scorpio, where it is partially united with the broken western stream. More than 100 years ago, Sir John Herschel at the Cape, "rummaging the recesses" of Scorpio, found it full of beautiful globular clusters. It was somewhere here that the elder Herschel found the 'hole' in the heavens, which modern astronomers now recognize as one of the numerous dark nebulæ found in the Milky Way. The Pleiades rise in the late evening as the precursor of winter nights and of brilliant stars in their well-known constellations.

Announcements

DR. PAUL C. MANGELSDORF, vice-director of the Texas Agricultural Experiment Station, has been appointed professor of botany in Harvard University and assistant director of the Botanical Museum.

DR. WILLIAM CRAMER, British delegate to the International Cancer Congress at Atlantic City in September 1939 and for more than twenty-five years a member of the Imperial Cancer Research Fund, London, has joined the staff of the Barnard Free Skin and Cancer Hospital in St. Louis.

A FURTHER modification in the terms on which enemy aliens can be released from internment was announced by Sir John Anderson in the House of Commons on August 23. In the White Paper setting out the conditions of release, scientific workers and others with academic qualifications were to be granted release if national work in their special fields was available for them. This qualification is now to be removed, on the recommendation of the Asquith Committee, which pointed out that "the benefits of science and learning were often indirect rather than direct".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Reversibility of the Denaturation of Silk Fibroin

SILK, as it occurs in the silk-glands of the silkworm (*Bombyx mori*), consists of two distinct protein systems, and, during the spinning by the worm of the double filament which serves as a building material for the cocoon, these two systems are forced through small orifices in a manner such that they respectively produce a central core or medulla of fibrous material and an outer layer or cortex of gum-like substance. The cortical protein material (sericin) is readily dispersed by hot solutions of soap or mild alkali, while the protein material (fibroin) forming the core of the filament is insoluble in water and is resistant to relatively strong chemical reagents; it is these properties of the extruded filament that partly account for its use as a textile fibre.

The nature of fibroin present in the silk-gland has been examined principally by Foà[1], Hirazuka[2], and Ongaro[3]. These workers found that the protein material obtained directly from the isolated silk glands is readily dispersed in water but equally readily coagulated by shaking, addition of acid, etc. The coagulation by mechanical action apparently occurs during the passage of the secretion from the worm to the outside air. The coagulation of silk fibroin is considered by Ongaro to be irreversible, and this conclusion has not been contradicted by any experimental work up to the present time. Harris and Johnson[4] have obtained water-soluble preparations of fibroin by dissolution in concentrated salt solutions and subsequent dialysis, but these workers conclude that the preparation is one of chemically degraded fibroin.

During an investigation of the solubility of fibroin in various solvents, we found that solutions of fibroin in cupriethylenediamine reagent, neutralized by acetic acid to *p*H 7·5 approximately and treated with solid sodium chloride to about two thirds saturation, yielded a mucilaginous precipitate readily soluble in water. The aqueous solutions of fibroin thus obtained behave similarly to those obtained directly from the silk-gland by Ongaro. Thus coagulation occurs extremely readily on mechanical agitation or addition of dilute acid. An aqueous solution of concentration 2·2 per cent gave an optical rotation of $[\alpha]^{20}_{D}$–42·7°; Ongaro found $[\alpha]^{24}$–39°. It would therefore appear that the coagulation of fibroin can be considered as a process of denaturation and that the denaturation is reversible.

The reversion of heat denaturation in proteins has been accomplished to some extent by Michaelis and Rona[5], Spiegel-Adolf[6] and Wilhelm[7], while the conversion of fully denatured hæmoglobin into a water-soluble form to the extent of 80 per cent has been demonstrated by Anson and Mirsky[8]. The present method of renaturation is of interest owing to the well-defined conditions under which the reversion is achieved. Attempts to apply the method to heat-coagulated ovalbumin have so far proved unsuccessful.

Examination of the products afforded by the renaturation of fibroin of various origins indicates that the fibroin of commercial raw silk is heterogeneous in composition.

A detailed description of the above experiments will appear elsewhere in due course.

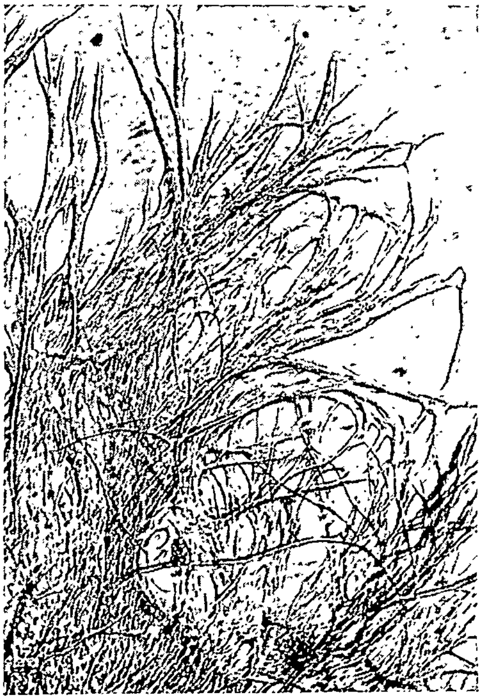
Architecture of Colonies of a Pure Strain of Fibroblastic Sarcomatous Cells derived from a Dibenzanthracene Mouse Tumour

DURING the *in vitro* cultivation of a pure strain of fibroblastic sarcomatous cells derived from a spindle cell sarcoma originally induced by 1 : 2 : 5 : 6-dibenzanthracene in mice[1] a special architecture of the colonies of these sarcomatous cells has been noted. When grown in Carrel flasks in a hen plasma coagulum and fed with either Heparin hen plasma[2] or a hen serum–chick embryo juice–Tyrode mixture, in which the embryo juice concentration is kept low, the cells regularly show a tendency to grow out in close association with one another, and to form ribbon-like strands or even broad sheets which resemble very much the epithelial type of growth *in vitro*. These ribbons frequently arborize and their branches often join up with one another, forming loops and bridges enclosing the coagulum, as shown in the accompanying illustration. The sheet-like growth is found especially at the interface coagulum-glass, whereas the cell ribbons occur also within the clot. This architecture seems to be very characteristic, and has been maintained through frequent passages. It permits the diagnosis of such a sarcomatous colony with the naked eye, being vastly different from the architecture of normal fibroblast colonies; aided by the more highly refractive cytoplasm of the tumour cells it brings the whole colony much more into relief against the background of the coagulum so that, even for the naked eye or under low power, the entire edge of the colony is sharply and clearly defined.

These sarcomatous cells scarcely liquefy the hen plasma coagulum. If, however, the culture is fed with embryo juice instead of the above treatment the cells grow out in a more scattered way, forming long chains of cells arranged in what can aptly be described as 'head-tail' position, the individual cell having a very definite spindle shape. It is known that liquefaction of the clot is aided by the enzymes present in embryo juice. It is therefore suggested that the characteristic colony architecture described above is related to the inability of the sarcomatous cells to liquefy the coagulum, the individual cell, unless aided by embryo juice, being unable to penetrate the coagulum to any extent, but when joined with fellow cells to form a ribbon or a sheet, will do so at a relatively slow rate. This architecture does not seem to have been commented on by other workers who used similar culture material[3,4,5]. But Earle[6] in a paper dealing with strip-shaped explants gives a photograph of a methylcholanthrene sarcoma culture the growth zone of which bears some resemblance to the ones described here.



PART OF LIVING SARCOMA CULTURE (*Fl* 9869 *c*) AFTER 163 DAYS *in vitro*; 32 DAYS AFTER LAST TRANSFER (× 55).

In the light of the difficulties which have been experienced by other workers,[4,5] in maintaining such sarcoma cultures over long periods, it is worth noting that the cell strain on which the above observations were first made was, in 1937, carried on *in vitro* for 131 days. The observations were confirmed in a new series of cultures which were started in January 1940 from the same tumour strain which was then in the 129th animal passage, its histological features being unchanged. These cultures, again of a pure 'fibroblastic' type, have now been carried on for 215 days so far, without impaired vitality. At intervals (after 134 and 181 days *in vitro*) some cultures were inoculated into mice (a single culture or part of such into each individuum), in some of which the original sarcoma was reproduced, that is to say, that in spite of the complete heterogenous medium in which the cells had lived and grown, they have preserved the property of forming a spindle cell sarcoma in mice.

Details of these experiments will be given elsewhere.

I wish to thank Dr. Woodhouse for supplying the tumour material. Thanks are also due to the Birmingham Branch of the British Empire Cancer Campaign for a grant which in part supported this work.

Cultivation of the Agent of Fowl Leukosis *in vitro*

THE following is a brief account of the cultivation of the causative agent of fowl leukosis (hæmacytoblastosis strain *T*1, Engelbreth-Holm) in the presence of normal cells proliferating *in vitro*.

Experiments were conducted as follows:

(*a*) Bone-marrow and fragments of heart muscles of chick embryos or of adult fowls were cultivated separately in plasma of leukotic fowls diluted with Tyrode 1 : 2. Before being used, the plasma was freed from cell elements by thorough centrifugation. Cultivation was carried out in flasks according to the standard method of Carrel. The cultures were washed and fed every third day with normal plasma (method Parker-Fischer). After 2, 3 and 4 weeks cultivation, flask cultures as well as control flasks, containing the same medium as the experimental flasks, but without any tissue, were inoculated into young fowls. Inoculation of flask tissue cultures resulted in typical leukosis. Of 7 cultures inoculated after 2 weeks cultivation, 4 were positive; of 3 three-week-old cultures, 2 proved positive; of 2 four-week-old cultures, 1 was positive. Inoculations with the control flask material always gave negative results. Leukotic agent survives *in vitro* in the presence of fibroblast cultures as well as in the presence of bone-marrow cells. Half the above experiments were carried out with bone-marrow cultures, and half with fibroblast colonies originating from cardiac muscle. The proportion of takes was approximately equal in both cases. Although the above experiments demonstrate beyond doubt the possibility of survival of agent in the presence of proliferating normal cells, we undertook further experiments because of the irregularity of the above results.

(*b*) Colonies of fibroblasts derived from normal heart were planted in Carrel flasks after having been bathed for one hour in cell-free ultrafiltrates (Berkefeld filter *N*) of heart and spleen extracts of leukotic fowl. Normal chicken plasma diluted with ultrafiltrates in proportion 1 : 2 was used as culture medium. Cultures were washed and fed with normal plasma. Altogether, four experiments were carried out, including a total of eight flasks ; the content of each flask was inoculated into two chicks. The fluid medium was injected intravenously, the solid material intramuscularly. Tissue-free control flasks were inoculated at the same time and in the same way. Of four cultures inoculated after two weeks cultivation and four cultures inoculated after four to five weeks cultivation all proved positive. Of sixteen chicks inoculated, fifteen died of leukosis. The fowls died twelve to twenty days after inoculation. Inoculations with the control flask material always gave negative results.

In further experiments, original cultures were transferred into fresh medium after thirty days cultivation. Up to date we have succeeded in maintaining such cell colonies for 86 days *in vitro*. Passages were made every second week. Cultures of first, second, third and fourth passage, that is, after 6, 8, 10 and 12 weeks cultivation, were each injected into two chicks. The washing fluid of these cultures, after passing through an ultrafilter, was inoculated at the same time as the cultures on two other chicks. Inoculations (into a total of eighteen fowls) gave positive results in all cases.

Our experiments show that under suitable conditions it is possible to cultivate leukotic agent in the presence of cultures of normal fibroblasts as well as in cultures of bone-marrow.

The fact that the agent which has the power to cause continuous multiplication of primitive blood cells in the body needs only the presence of non-specific mesenchyme cells for its reproduction *in vitro* need occasion no surprise in the light of the previous experiments with cultures of leukotic tissues. Contrary to Furth and Breedis[1], who were led by their experiments on cultivation of leukotic fowl tissues to conclude that "oncogenic viruses multiply *in vitro* only in the presence of cells on which they confer neoplastic properties", we were recently able to show in studies carried out on leukotic tissue cultures[2] that there is no relation between the infectivity of the culture and its cellular composition. Blood cell cultures and cultures of bone-marrow which, in the course of passages, are transformed into pure fibroblast colonies were in our experiments as pathogenic as blood and bone-marrow cultures in the earliest stages when they still contain numerous primitive blood cells. Furthermore, in confirmation of Ruffilli's[3] results, we proved that the cultures of myocardium of a leukotic fowl which we cultivated through 47 passages during a period of six months, and which already in the first passages are practically free of any round cells, retained their infectivity throughout.

Experiments with cultures of tissues from leukotic fowls did not, in our opinion, furnish sufficient proof that leukotic agent is capable of surviving and multiplying in the presence of non-specific mesenchyme cells because the possibility, however slight, that some primitive blood cells from the original leukotic tissues might survive in cultures could not be absolutely excluded. The experiments reported here furnish decisive proof of the fact that the agent producing leukosis in the fowls does not require the presence of primitive blood cells for its cultivation *in vitro* ; leukotic agent can be cultivated in the presence of common fibroblasts just like numerous non-carcinogenic viruses.

Details of our work will shortly appear elsewhere.

These investigations have been supported by a grant from the Lady Tata Memorial Trust.

A New Cardiac Glycoside?

Asclepias curassavica is very common in Queensland and parts of New South Wales and has often been suspected of poisoning stock. On testing, it was found that the liquid extract obtained by macerating 2 lb. of the plant in cold water killed a 600 lb. steer in fifteen minutes.

Investigation of the plant has shown that the toxic principle is a mixture of glycosides of the cardiac type. This mixture can be resolved into a chloroform-soluble group and a water-soluble group ; from the chloroform-soluble group a crystalline glycoside m.p. 130° C. has been obtained—this glycoside gives with concentrated sulphuric acid an orange colour changing to purple on contact with air and in the Kiliani test the acetic acid layer becomes green, a purple ring developing at the junction of the two layers on standing. The water-soluble group consists of an amorphous mixture which is hygroscopic and very soluble in water—this material gives a deep emerald green colour with concentrated sulphuric acid. Positive Legal and Baljet tests are obtained with the glycosides of both groups. The glycosides of both groups when tested in very small dose on frogs caused death in half an hour, the ventricles being arrested in systole—characteristic heart tracings were obtained. The action of the plant enzyme on the glycosides of the water-soluble group has also been investigated.

Allopolyploid Nature of the Wild Tetraploid Watercress

THE geographical distribution and behaviour of diploid, triploid and tetraploid watercress was described some years ago by one of us (I. M.[1]). The triploid was shown to be a hybrid between diploid and tetraploid, but the origin of the tetraploid was unknown. It was thought to be an autopolyploid partly on account of its close resemblance to the diploid and also because of the absence of an obvious alternative, Nasturtium being now generally regarded as a monotypic genus. The absence of multivalents from meiosis was thought to be due to the very small size of the chromosomes. That another interpretation must be put upon the facts regarding the tetraploid has now been shown by the following method.

In 1938 the original stocks used by Manton were communicated to Howard who treated young seedlings of the diploid with 0·5 per cent colchicine solution and thereby produced a genuine autotetraploid. It was at once apparent that this plant was not identical with the wild tetraploid. It showed all the features of darker colour, fleshier leaves and larger organs, characteristic of autopolyploids in general; but it did not show the slow growth, straggling habit and details of fruit shape that had been noted in the wild tetraploid. Moreover, its fertility was reduced and when crossed with the wild tetraploid the hybrid was highly sterile.

Investigation of meiosis by Manton has shown that whereas the wild tetraploid, as previously reported, forms 32 bivalents (the diploid forms 16), the real autopolyploid forms many quadrivalents, thus disproving the idea that their presence or absence has anything to do with chromosome size. The hybrid between wild tetraploid and the autotetraploid forms no quadrivalents but only trivalents, bivalents and a large number of univalents. The hybrid between wild tetraploid and diploid *Nasturtium officinale* (that is, the triploid previously described) forms, at least in the majority of pollen mother cells, 16 bivalents and 16 univalents. It is therefore clear that each gamete produced by the wild tetraploid contains 16 chromosomes (half its total complement) which are homologous with those of the diploid and artificial autotetraploid *N. officinale* and 16 other chromosomes which are non-homologous. The identity of the non-homologous chromosomes is not yet known, but it is expected that they will be found to belong to a species of the related genus Cardamine, particularly as the seeds in the wild tetraploid are uniseriate as found in Cardamine and not biseriate as found in diploid and artificial autotetraploid *Nasturtium officinale*.

In any event it is quite clear that 'wild tetraploid watercress' is not an auto- but an allo-polyploid, and in our opinion taxonomists would be well advised to treat it as a new species. It is hoped that a fuller account with illustrations will be published later.

Shortage of Lavender Oil

In Nature of August 10, p. 193, in a note on "This Season's English Herbs", the statement is made—"a fair yield of English lavender oil may be expected for this season; more of the flowers will go to the still and less to Covent Garden in bunches for street vendors, and thus at least part of the shortage due to the lack of French oil will be made good".

When comparison is made between the acreage devoted to lavender cultivation in Great Britain with that devoted to a similar purpose in France, plus the acreage of the areas from which wild lavender is habitually collected for distillation—to say nothing of the acreage devoted to the cultivation of the hybrid lavandin—it is obvious that, quantitatively, increased distillation of English lavender will make good the deficit only to a very trifling extent. I believe that, normally, France distils about 150 times as much lavender oil as we do. Commercially, English lavender oil is also unable to make good the deficit because of the very high price it commands compared with the French oil.

Fortunately, in recent years lavender cultivation has been taken up in Kenya, and quite a good oil is produced at a price comparable with the French. Lavender oil is also distilled in Western Australia, and there is a *Lavandula Stoechas* oil of Portuguese origin available.

It seems certain, however, that the production of lavender water and other lavender-scented toilet requisites in Great Britain will tend to diminish and that prices will tend to rise. The sales tax will also tend to limit consumption. This is much to be regretted on grounds of public hygiene, since the antiseptic value of lavender oil, according to the well-known work of Cavel, is superior to that of phenol (carbolic acid).

Formation of Protective Films

In Prof. N. F. Mott's interesting article in Nature for June 29, p. 996, he states that "in some metals, notably aluminium, oxidation stops altogether when the film has reached a thickness of the order of 10^{-6} cm., the protective films thus formed preventing further attack".

In measurements of the electrical resistance of such films[1] I obtained the following roughly comparative results:

Film resistance immediately after emery polishing under paraffin	1,651 ohms.
After 8 hr. exposure to moist air	2,501 ,,
Heating 8 hr. at 160° C. in air	4,511 ,,
Heating 65 hr. at 300° C. in air	8,381 ,,
Anodic oxidation film..	26,300 ,,

These increases in resistance would seem to indicate closer packing made possible by recrystallization, and to show that the final film thickness on aluminium is not greatly affected, even by long exposures at higher temperatures; this is in accordance with Prof. Mott's theory.

There is further the interesting suggestion that the oxide films of aluminium and zinc will dissolve metal. This is in contrast to a cuprous oxide film, and a means by which it can be distinguished from the amorphous metal which, according to Finch[2], will dissolve metal crystals, whereas the oxide will not.

RESEARCH ITEMS

Joking Relationships

THE custom whereby two people on meeting are required to joke, even to obscenity, with one another has been reported frequently from Africa, but is also well known as occurring among primitive peoples in other parts of the world. The general principles of this relationship have been examined by A. R. Radcliffe-Brown (*Africa*, **13**, 3; July 1940) who suggests that it must be taken in conjunction with the custom of avoidance. Frequently a man is on joking terms with his wife's brothers and sisters, but there may be partial or complete avoidance of his wife's parents. These relations then express states of social disjunction and conjunction set up by marriage. The basis of the distinction is the generation, and sometimes seniority within the younger generation. At the same time, while the preceding generation has to be treated with respect, very often the joking relation subsists between grandchildren and grandparents. It is to be noted too that the relation is found between nephew and mother's brother or other relatives, but the father's brothers are treated with respect. In addition to the tie of marriage affecting this relation, there is that of adoption and the alliance by exchange of goods or services which may also be connected with avoidance. An alliance by blood-brotherhood may be a joking relationship as among the Zande. The joking relationship in some ways is the exact opposite of a contractual relation. It must also be distinguished from the relations set up by common membership of a domestic group, a lineage or clan, each of which has to be defined in terms of a whole set of socially recognized rights and duties.

Gypsies of the Sárrét (Hungary)

IN an account by Istvan Nagy of Budapest (*J. Gypsy Lore Soc.*, Ser. 3, **19**, 3–4; 1940) of the gypsies of the Sárrét as they are to-day it is pointed out that the ubiquity of the gypsies in a village is no true index of their numbers. It is due to their volatile and active character in which they recall the activity and noisiness of the people of the south. Their life is entirely different from that of the peasant and causes mistrust, even though the peasant is extraordinarily tolerant. The house of the gypsy is wretched and small compared with that of the peasant. Mud-walled and clay-roofed, only in the newer dwellings are there even two rooms and roofs of reed or straw. The floor is of well-trodden earth, which is kept smooth and yellow with clay mixed with horse manure. The walls are whitewashed inside and plastered with chaffy mud outside. Heating is difficult if not impossible in winter, when the gypsies rarely leave the house but avoid intense cold by remaining indoors sheltering in their eiderdowns. When they gave up their nomadic life to settle in the villages, their traditional crafts disappeared largely owing to their lack of technical skill as compared with the trained smith or other worker. Now they engage in agriculture or horse trading. Their wealthiest men are horse traders, and to own a horse is matter for ostentation. Their standard of wealth is low, and they are improvident, squandering their earnings as soon as paid. Beside the horse they have no domestic animals. The favourite food is carrion-animals and poultry dead of disease, which they manage to obtain whatever the measures taken by the authorities to prevent them. In the matter of dress, their clothes bought secondhand and altered to suit their individual taste, are in this sense better in cut and original quality than those of the peasant. They are also brighter in hue. The women wear the most vivid reds and greens, and their hair is gay with ribbons and gaudy kerchiefs. In the hottest weather they wear three or four skirts.

Phenological Records in Great Britain

DESPITE the war-time difficulties of organized voluntary field work, both the Royal Meteorological Society and the British Empire Naturalists' Association are continuing to collect records of seasonal migration of birds, flowering of plants and similar events in Great Britain in the hope that the continuity of phenological work may not be broken. The British Empire Naturalists Association is summarizing the records sent in from its twenty-odd branches in a duplicated "Branch News", privately circulated. A new issue covering the first half of 1940 includes the rare marsh-sandpiper at Slough, Bucks., where a fairly constant watch also records such passage of birds as the wood-sandpiper, spotted redshank, Iceland gull, greenshank, whimbrel and sanderling. Bird migration began earlier than usual this spring, and there were many wild geese in the south of England. Unusual numbers of swifts were noted in Derbyshire, but fewer house-martins. In the south, the stag-beetles were very common, while the comma and white admiral butterflies have extended their range in the Sherborne district of Dorset. The Royal Meteorological Society has circulated to its numerous phenological observers a preliminary report on the 1939 field observations. With regard to hibernating brimstone butterflies, the date of emergence depends upon the accumulating warmth in their respective shelters, so that no general condition can be predicted; the males appear before the females as with most insects, but if the favourable weather conditions deteriorate they return to hibernation. The capricious appearance of these hibernated butterflies cannot form a reliable index to seasonal changes. A phenological organization is being set up in Canada, where the country has been divided into zones and selected species have been chosen for observation.

Note of the Anna Hummingbird

THE dive note of this American hummingbird, *Calypte anna*, is distinctive. It is produced by the male bird on the instant when it turns upwards after making a steep and rapid descent. The origin of this note has been argued about; but generally it is considered to be produced by flight or tail feathers. Thomas L. Rodgers has settled the point, as the 'drumming' of snipe was settled long ago, by simple experiments with various feathers (*Condor*, **42**, 86; 1940). Individual feathers and whole tails and wings were held in swift air currents, with the result that the only promising response came from the outer tail feathers, which are narrower than the rest, have a stronger vane and are curved outwards for half their length. These feathers attached to a slender strip of bamboo, when whipped through the air, produced a note almost identical with that of the bird. Immature males were found not to produce the note, and examination showed that the outer tail feathers in juvenile males were broader, especially towards the tip, and had a softer vane. They did not produce a note with the bamboo whip. The experiments might be repeated with the feathers, adult and juvenile, stuck into a cork whirled at the end of a string, the method which demonstrated the 'drumming' of snipe.

Feeding Habits of the Japanese Beetle

The Japanese beetle (*Popillia japonica*) was first found in the United States in 1916 at Riverton, N.J. It has, in the meantime, spread into six States, and by 1938 the areas continuously infested by this insect covered 15,100 square miles. Circular No. 547 of the U.S. Department of Agriculture (May 1940) by I. M. Hawley and F. W. Metzger enumerates 275 species of plants known to be fed upon to a greater or lesser degree by the adult beetle. In feeding, it normally eats out small portions of the leaf surfaces, leaving the veins untouched. The leaves thus skeletonized turn brown and usually fall from the plants. The beetle is gregarious and often collects in masses or 'balls' and feeds extensively on such preferred fruits as apples and peaches until only the core or stone remains. The feeding behaviour varies with atmospheric humidity and temperature. When the latter is below 70° F., feeding is light: it is heaviest between 85° F. and 95° F., but above 95° F. it is light. When relative humidity is below 50–60 per cent, the beetles fly actively but feed relatively little. Above 60 per cent humidity feeding is vigorous. The one known factor that makes many plants attractive to *Popillia* is the high content of reducing sugar in the part of the plant usually fed upon. Of the many plants liable to attack, severe injury results to many kinds of fruit trees, also certain Malvaceæ, soybean, elm, poplars and some kind of grape, etc. To many other plants injury is moderate or slight. Some plants such as geranium, castor-beans and bottle-brush buckeye are reported to kill the beetles after feeding on them.

Parasites of Chafer Larvæ in Africa and France

L. Andre Moutia, assistant entomologist, department of Agriculture, Mauritius, has recently discussed the above subject (*Bull. Entomol. Res.*, June 1940). He describes an extensive survey, lasting eighteen months, that was carried out in Zanzibar, Algeria, Morocco and parts of France. The object of the survey was to obtain a supply of parasites of Melolonthid larvæ or 'white grubs'—for furthering the control of these latter creatures in Mauritius where the species *Phytalus smithi* has been a long-standing pest of sugar-cane. In Zanzibar it was disclosed that white grubs are of no special economic importance and also their rate of infestation by parasites is very low. In Algeria no effective means of control of this pest was obtained, and in France control is mostly done by flooding. In Morocco, parasitism by a Tachinid fly *Dexiomorpha picta* Meig., averaged 1·5 per cent but ranged up to as much as 16 per cent locally. The bionomics of this parasite is fully discussed and the morphology of the various stages in the life-cycle are described and figured. Larvæ were transmitted to Mauritius and kept in cold storage at 4–6 C. and the survival rate was 49–80 per cent. The percentage of flies emerging from the parasitized white grubs ranged from 10 to 26·9. It appears that the Dexiomorpha is the only Tachinid worthy of further attention, and it is very desirable that importation of it in large numbers should go on so as to render available sufficient quantity for release in Mauritius. The species in question is stated to be the most promising parasite yet discovered.

Red Core Root Disease of Strawberry

In recent years strawberry crops in Scotland have been seriously reduced by 'Lanarkshire disease', characterized by withered leaves, decayed roots, and a red colour in the central cylinder of the roots. A similar disease has been reported from the United States. Outbreaks of the disease have now been reported in various places in England, and the fungus responsible has been isolated in pure culture by C. J. Hickman (*J. Pom. & Hort. Sci.*, 18, 89; 1940). The morphological and physiological characters of the organism have been described and its pathogenicity proved experimentally. The name *Phytophthora Fragariæ* has been assigned to it; it differs from all previously described species of Phytophthora. The severity of the disease is closely related to soil moisture conditions, being worst where water content is high on account of impeded drainage. The strawberry roots become invaded at their tips, and the fungus passes backward through the central cylinder, which becomes reddened. This has given rise to the name 'red core disease'. The plant remains small during late spring and early summer, and the foliage wilts and finally dies. None of the common varieties grown in Great Britain is immune, though Pillnitz, Early Cambridge, and Oberschlesien are fairly resistant. Four new seedling varieties bred in Scotland have been found to be immune. The breeding of immune varieties promises to be the only reliable means of control, though there is some indication that the disease may be inhibited by soil alkalinity.

Evolutionary Chromosome Change in Sciara

C. W. Metz, of the Department of Embryology, Carnegie Institution of Washington, read a paper on this subject at the Eighth American Scientific Congress. On the assumption that evolutionary changes are initiated in the chromosomes, an attempt is being made to throw light on such changes by a study of both spontaneous and induced chromosome alterations in fungus flies of the genus Sciara. A comparison of the phenomena observed in Sciara with those found in Drosophila has revealed striking differences which may have evolutionary significance. As shown by the work of Dobzhansky, Sturtevant, Bridges and others, spontaneous chromosome changes in Drosophila, as detected both in wild strains and in species hybrids, consist mainly of gross chromosome rearrangements such as inversions and translocations of chromosome segments. Minute modifications are relatively rare. In Sciara, on the other hand, the situation seems to be just the reverse. Minute modifications, which appear to represent small deficiencies and duplications of the chromatic disks, are detected frequently in wild strains and in species hybrids, whereas gross rearrangements appear to be almost entirely lacking in the material studied (of four species and one species hybrid). These results suggest that there is a difference in the underlying chromosome mechanism in the two genera and that evolution may possibly be following different trends in the two. Experimental studies on the nature of changes induced by irradiation are being used to throw further light on the problem. The latter, carried out in co-operation with R. D. Boche and Martha Lee Bozeman, have shown that in Sciara gross chromosome rearrangements are readily secured by irradiating sperms, but that few if any modifications are induced by irradiating eggs (at least in their later stages). In these eggs the chromosomes are in an apparently typical prophase condition, consisting of long threads (tetrads) which, from analogy with other organisms, should be sensitive to irradiation. A special effort is being made to ascertain what physical conditions in the nucleus are responsible for the resistance in the present case, in the hope that this may throw light on the mechanism underlying rearrangement or other modification of chromosome materials.

Genetical Studies on the Lady-Bird

Y. Hoshino (*J. Genet.*, 40, 215–228 ; 1940) shows that the spots and colour of the elytra of ladybird beetles are inherited as an autosomal multiple allelomorphic series. The varieties in this series are *succinia*, *axyridis*, *spectabilis*, *conspicua*, *forficula*, *transversifascia* and *aulica*. Heterozygotes involving *succinia* or *axyridis* can usually be distinguished from the corresponding homozygotes.

Plasticity Conditions for the Formation of Faults

This subject is considered further in a second paper by K. Sezawa and K. Kanai (*Bull. Earthquake Res. Inst.*, Tokyo Imperial University, 18, Part 1 ; March 1940). They investigate mathematically the stress and strain distributions in a surface crustal block bounded by one original fault, the plastic condition being taken only in the sense of maximum shear stress. The idealized problem is, however, chosen only as a working hypothesis, and the treatment of a block bounded by many original faults may be a more general one ; also a somewhat similar result may be possible with a folded crust. As a result of this and the preceding investigation (Nature, July 27, p. 136) it appears that, although a normal fault is formed in a crustal block bounded by original faults, the origin of the reverse fault is not restricted to local conditions but is related to the deformation of the entire earth, particularly in its early historical stage. The authors conclude that whereas the faults found in the Japanese Islands would be of reverse or normal type, those that neighbour the Japan Trench, or large faults in the continent of Asia, would probably be of reverse type.

Japanese Earthquakes, January–June 1939

During the first half of 1939 there were no violent earthquakes felt in Tokyo and none which the Japanese call strong. (Seismometrical Report of the Earthquake Research Institute, Tokyo Imperial University, 1939, Part 1–2 ; January 1–June 30, 1939). Altogether there were 26 earthquakes felt in Tokyo during this period of which 23 were classed as slight, 2 as rather weak and one, on the tenth of March, as weak. This latter had an amplitude of 262 μ in Tokyo with a maximum acceleration of 0·19s. Its epicentre was 36·15° N., 137·91° E., to the west-north-west of Okiziku and north-north-west of Tokyo. With only three exceptions, the epicentres of the 26 shocks lie roughly in the shape of a letter L with the angle near the epicentre just mentioned, and the upright branch running roughly north-east. Both branches extend into the sea bed.

Earthquakes of the U.S. Atlantic Coastal Plain

This subject is discussed by N. H. Heck (*Bull. Seis. Soc. Amer.*, 30, No. 2, April 1940), who states that the seismicity is definitely related to the geological structure of the region between the fall line and the coast. In this region earthquakes of Rossi - Forel scale intensity 5 or over are rare except near Charleston. Forty-five epicentres with repetitions and about 90 distinct earth shocks have been distinguished outside the Charleston-Summerville area though undoubtedly some have escaped notice in the past. The double epicentre Charleston S.C. earthquake of 1886 was one of the greatest which have occurred in the world. Since this great earthquake, shocks from the same epicentres have persisted to the present time with only 8 years when no shocks were recorded, though the numbers per annum of these have considerably fallen off since 1893. The author suggests that there should be an active seismological station set up in Virginia and at least one other farther south to assist in the location of the considerable amount of earthquake activity in the Appalachian region. In the absence of such stations, an appeal is made to geologists in the districts where earthquakes occur to send immediate information to the U.S. Coast and Geodetic Survey at Washington, D.C.

Photographic Proper Motions in the Præsepe Cluster

P. C. Chaudhuri has investigated the proper motion of the members of the Præsepe Cluster (N.G.C. 2632) (*Mon. Not. Roy. Astro. Soc.*, 100, 5 ; March 1940). Van Rhijn and Wassink have already discussed the proper motions of the members of the cluster, and the latter found that the centennial proper motion was 3·7″ in position angle 249°. Accurate proper-motion data have been obtained by the Radcliffe plates, which have the great advantage of a long-time interval of 30·1 years between the early and the new plates. The measuring machine is of the Repsold type and furnishes measurements in one direction only. The scale of the micrometer is such that one unit is equal to 0·00025 mm., that of the Radcliffe telescope being given as 1 mm. = 30″ ; hence the scale adopted in the present paper is one unit equal to 0·0075″ in 30·1 years. It was a simple matter to separate the cluster from the non-cluster stars. When the equatorial components of proper motion are plotted, the cluster stars show a marked concentration around a certain point while the non-cluster stars exhibit a scattered distribution. It was found that there were a hundred cluster stars in the region covered by the plates. Of stars brighter than magnitude 9 there was only one classified as non-cluster, and between magnitudes 9 and 11 there were 39 members and 13 non-members. There is a decided preponderance of brighter stars as members of the cluster. The proper motion components of the hundred cluster stars are shown in Table ii, arranged in eight groups according to magnitudes, and there is practically no magnitude error in the components. The centennial group-motion is 3·9″ in position angle 242·9°.

SCIENTIFIC AND INDUSTRIAL RESEARCH IN AUSTRALIA

THE thirteenth annual report of the Council for Scientific and Industrial Research, Commonwealth of Australia, covers the year ending June 1939 (Canberra: Commonwealth Gov. Printer, 4*s*. 6*d*.). The Council was established in 1926 by the reorganization of the existing Institute of Science and Industry, and the powers and functions of the Council are defined by the Science and Industry Research Act, 1920–39. They include the initiation and carrying out of research in connexion with, or for the promotion of, primary and secondary industries, the training of research workers, the making of grants-in-aid of pure research, the testing and standardization of scientific apparatus and instruments, the carrying out of scientific investigations connected with standardization and the establishment of a Bureau of Information relating to scientific and technical matters. The report refers to progress in the erection of the National Standards Laboratory and the Aeronautical Research Laboratory. The erection and equipment of a laboratory for the Fisheries Section was completed during the year at Port Hacking, south of Sydney. Reference is made in some detail to investigations on plant introduction, pasture plant breeding and investigations on pastures. Other investigations of the Division of Plant Industry cover experiments planned for a period of five years on the root rot of wheat, as well as seed-bed experiments on the control of downy mildew of tobacco which refer to the successful results obtained with benzene vapour and also with Shirlan compounds and alum-lead acetate as cover dressings. Studies on the nature of the virus diseases of Australian potatoes have also been continued by the Division.

The Division of Economic Entomology records the successful introduction and establishment of some parasites of insect pests and of one insect introduced to control the weed lantana. Improved methods of controlling the common household pests, silver fish, meat ants and small black ants have been developed during recent years. During the year, sheep blowfly investigations have concentrated attention on the study of attractants and repellants, the investigation of poisons and examination of dressings. Investigations on orchard and fruit pests included a study of the oriental peach moth and work on phenothiazine and its derivatives to control the codling moth. Special attention has been given to the problem of the direct control of termites, and laboratory and field experiments have indicated some of the reasons, apart from their higher toxicity, for the superiority of arsenicals over silicofluorides. Investigations on weeds have included a study of the relation between certain physical properties of translocated sprays and their rate of penetration into leaves, involving a study of the wetting ability of a spray.

The Animal Health Research Laboratory at Belmont has continued its investigations on pleuropneumonia in cattle as well as on mastitis in dairy cattle, while the work of the McMaster Animal Health Laboratory has included investigations on the effect of nicotine sulphate on *Hæmonchus contortus*, as well as on the efficiency of anthelmintics, including phenothiazine. Other work has been concerned with studies on fleece chemistry including the wool fibre, the properties of wool wax, the suint and the dirt, as well as on the physical characteristics of wool, on the ecto-parasites of sheep, and sheep dipping and investigations on foot rot, coast disease of sheep, and cobalt- and copper-deficiency in ruminants. The work of the Division of Soils has included an investigation of the fertilizers used in Australia as well as studies in soil microbiology.

The Commonwealth Research Station at Merbein, Victoria, has continued its studies of soil preservation and reclamation; the work has included the preservation of soil fertility, studies in viticulture and fruit processing and examination of new fumigants. At the Irrigation Research Station, Griffiths, in New South Wales, studies on plant nutrition and also on the root system of plants with special reference to citrus fruits have been undertaken. Marked developments have also taken place in the work of the Division of Forest Products; a new Section for Veneers and Plywood and the completion and equipment of a laboratory for experimental pulp and paper studies are announced. A timber handbook has been prepared for publication to provide engineers and architects with tabulated data on the strength properties of Australian timbers in a form suited for the designer. Service tests have been continued on a large number of wood preservatives, and laboratory investigations have indicated that low concentrations of boric acid render susceptible sap wood immune to Lyctus attack, the lethal concentration being about 0·12 per cent. Details for commercial treatment have been developed and successful results obtained on commercial plants erected in Queensland. Other investigations have covered the glueing characteristics of Australian timbers and the testing of glues.

Investigations on food preservation have covered a wide range, from chilled beef and the use of ozone as a preservative in the ripening or conditioning of beef cuts to the completion of a survey of wastage of oranges in Australia and mandarins in New Zealand. The effects of maturity at picking time, district, application of boron to the tree and to the soil, delayed storage and temperature storage are being studied with Jonathan, Delicious, Democrat and Granny Smith apples, and factors associated with wastage in many varieties of pears in New South Wales are being investigated. The conclusion that gas storage can increase the storage life of less mature fruit, but may have a reverse effect on more mature fruit, has been drawn from experiments with pears as well as from experiments with peaches and plums. Other investigations of the Division have been concerned with the preparation and preservation of fruit juices and with can lacquers, and to discover corrosion-resisting, non-tainting lacquers suitable for internal application to tin-plate containers. The smoking of fish, the export and storage of eggs and the permeability to water of wrapping materials have all been handled by the Division.

Fisheries investigations have continued on tuna, as well as on pilchards, etc., and the determination of the sources and degrees of fish spoilage.

The report also refers to the work of the Radio Research Board, of the Commonwealth Prickly Pear Board, to ore-dressing investigations and to the work of the Information Section.

ECOLOGICAL BASIS OF LAND USE AND MANAGEMENT*

By Paul B. Sears,
Oberlin College, Ohio

LAND use and management involve a wide range of human adjustments to environment. This range extends from purely physical problems on into those of social relationship. The only scientific rubric embracing such a wide field is that of ecology. This is not to assume for ecology any greater authority than other sciences possess, but merely the right to try to develop a symbolism and method suitable to its approach.

The ecologist conceives of the living community as a highly integrated expression of solar energy. The measure of ecological or biological potential is in the degree to which such energy is stored and utilized before its final loss through entropic change. The degree of organization of the soil is a concomitant aspect of biological potential. Efficient natural communities and mature soil, therefore, afford norms for judging human culture patterns as they affect the landscape.

Modern science has been applied chiefly to elaboration of finished goods from raw materials. It needs also to be applied to the conservation of energy and materials, and to distribution. No sound programme of land use and management is possible except on this basis. For reasons other than abstract political theory, I believe that such adjustments can best be made within flexible regional communities, with considerable local initiative. The emphasis in such communities must inevitably be less on profit and more on design.

The basis of adjustment lies in ecological diagnosis. Through a study of physiographic processes, climatic pattern, soil development, biological stabilization, and the water cycle it can readily be determined whether the biological potential of a given landscape is being lost or maintained under the impact of a particular human culture form. Technical remedial measures are frequently obvious; the necessary social changes more obscure and difficult.

The present trend of land use must be reversed to give a maximum of natural communities and a minimum of ploughland, the latter more carefully chosen and handled than at present. Intermediate areas, such as pasture, must be adjusted to actual need. Such a programme will eventually increase real wealth and the population capacity of the land. An important and immediate need is to lessen the pressure for cash income from land.

Studies are needed of mixed cropping plans which will simulate natural communities, and of methods of tillage and humus return which are less violent than those now in use and which more closely simulate Nature. A much wider strategic and incidental use of permanent vegetative cover in drainage ways, fence-rows, etc., is already discernible, and is justified ecologically. In the cultural realm much may be learned from the occasional human communities which have developed and maintained a sound working relationship with the landscape.

---

CHANGES IN THE BRITISH PHARMACOPŒIA

THE first of the war-time emergency supplements to the British Pharmacopœia, which was outlined in NATURE of June 8 (p. 889), became official on June 15. It is not improbable that a second addendum will be published later containing monographs on certain synthetic drugs of the type known as new remedies, for the supply of which Great Britain has hitherto depended upon foreign sources which are not now available. There is also a need for a third addendum to supply formulæ for sweetening preparations for use in place of sugar compounds; indeed, it seems desirable that standards should be laid down for such preparations as soon as it is convenient to do so, in view of the announcement by the Ministry of Food that no new permits to manufacturers to obtain sugar supplies can now be considered.

The addendum dealing with synthetic drugs would rechristen the products selected for inclusion; pharmacopœial names will take the place of the original proprietary names; thus "Doryl" will become "Carbachol"; "Fouadin" will be renamed "Stibophen" and "Coramine" will be officially called "Nikethamide". The selection for inclusion in the addendum will be made only from such drugs as are now being produced, or will shortly be produced, by British manufacturers.

The problem of substitutes for sugar compounds is less easy than would appear at first sight; it is not merely a question of sweetness; it is also desirable that so far as is feasible the substitute should be of the same density as the sugar preparation and should possess, in certain cases, preservative properties. In many instances no doubt saccharin or glycerin would serve the desired purpose so far as the sweetening factor is concerned, and it is interesting to note that saccharin is now manufactured on a large commercial scale in Great Britain and that up to the present medicinal glycerin has been obtainable at the same prices as were quoted before the War began; the by-product of the soap industry has been ousted from the prominent position it formerly held in respect to the manufacture of high explosives. What appears to be a valuable suggestion was made recently by a member of the Council of the Pharmaceutical Society, Mr. J. C. Young, who, in an address on the subject to a branch meeting of the Society, suggested that manufacturers who introduced new compounds should not use sugar but some alternative for it. By this means there would be an avoidance of change of appearance and taste of the compound in the event of it becoming necessary to forgo the use of sugar.

ORIGIN OF THE SOLAR SYSTEM

R. A. LYTTLETON has now prepared a detailed defence of his theory of the origin of the solar system against various criticisms urged at different times (*Mon. Not. Roy. Astro. Soc.*, **100**, 7 ; May 1940). In the short compass of the present note it is impossible to consider in detail the contents of the paper, which should be read by all interested in problems of cosmogony. A few outstanding points are worthy of special attention.

It will be recalled that the theory was first put forward in 1936 (*Mon. Not. Roy. Astro. Soc.*, **96**, 559 ; 1936). Luyten criticized various features of the theory, and, *inter alia,* pointed out that hydrogen would readily escape at high temperature from the filament from which the planets were evolved. Lyttleton shows that, while the lightest elements would escape from the filament or primitive planet, such gases would not necessarily escape from the sun. They would form a tenuous medium, possessed with angular momentum, through which the planets would move. As the planets would pick up lighter gases after their initial formation from the heavier elements, the presence of hydrogen on the major planets is no objection, as Luyten believed, to Lyttleton's theory.

Another important matter is the amount of energy required to remove the planetary material. Luyten and Hill pointed out that the energy necessary to generate the planets from the companion to the sun must have been so large that the visiting star would have required a velocity of the order of 100 km. a second. In these circumstances the centre of the ribbon from which the planets were formed would have possessed a velocity far beyond the escape velocity relative to the sun. In the present paper, Lyttleton deals with some simple quantitative results and shows that in his reply in an earlier paper it was unnecessary to postulate so large a relative mass for the intruding star. In fact, there is no justification for assuming that the energy could be supplied only by a star of exceptionally high mass.

Other points are dealt with, such as the objection to the complexity of the theory, which, Lyttleton shows, is not a valid objection. Nor can the difficulties regarding the filament be urged as serious when it is remembered that the generally accepted views concerning the development of the filament were current before he propounded his theory, and hence he is not responsible for them. He admits at the end of the paper that, while his own theory is not really open to any objection, this does not preclude the possibility that other explanations of the origin of the solar system may be devised.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned :

Part-time Teachers of Engineering Drawing (S.1), Electro-Technology (D.C.) (S.3), Theory of Machines (A.1), Engineering Drawing and Design (A.2), Electrical Engineering—Measurements (A.2), and Electrical Engineering—Distribution and Utilization (A.2)—The Principal, Twickenham Technical College, Egerton Road, Twickenham (September 4).

Assistant Secretary for Higher Education—The Secretary for Education, County Offices, Aylesbury, Bucks (September 7).

Deputy Director of Education—The Director of Education, Education Offices, Union Street West, Oldham (September 7).

Engineer to the Middle Level Commissioners—The Clerk to the Commissioners, Middle Level Offices, March, Cambs. (September 10).

REPORTS AND OTHER PUBLICATIONS

(*not included in the monthly Books Supplement*)

Great Britain and Ireland

Proceedings of the Royal Society of Edinburgh, Session 1939–1940. Vol. 60, Part 2, No. 17 : The Energy Levels of a Rotating Vibrator. By Dr. Ian Sandeman. Pp. 210–223. (Edinburgh : Robert Grant and Son, Ltd. ; London : Williams and Norgate, Ltd.) 1*s.* 3*d.* [128

LEADERSHIP IN RECONSTRUCTION

ONE of the most encouraging features of Prof. K. Mannheim's admirable study "Man and Society in an Age of Reconstruction" is the vista he opens out before us of the possibilities in the use of the study of society along scientific lines in the actual task of reconstruction. With a right conception of planning and the wise use of the appropriate technique, it should be possible to plan and to build a social order in which are preserved the freedom essential for creative work and moral and intellectual development and the harmony essential if men are to live together in an ordered society.

Prof. Mannheim's conception of planning, as of freedom, is dynamic. Man's needs change no less than the form in which those needs are expressed or served. Our task in this time of crisis and change is the dynamic one of bringing creative thought and constructive effort to bear, so that the organization of society is not left to chance or irrational forces but guided with the inspiration which comes from bringing all our available scientific energy and insight to bear on the understanding of the situation and the control of the determining factors.

The records of the War of 1914–18 show that we were able to look forward, even amid the preoccupations of some of its darkest years, and to plan and build for the future with such measures as the Education Act, the Representation of the People Act, the Sex Disqualification (Removal) Act and others of a like type, to which an admirable broadsheet of PEP (Political and Economic Planning) has directed attention. To-day the disturbance to the social and economic life of the country is even more profound. At the same time, the opportunities of reconstruction are opening up before us still more freely and widely. Democracy has a greater chance than ever of demonstrating its enduring value, its link with the imperishable elements in our moral heritage, by taking the expedients temporarily forced upon us by war, and with the necessary adjustments building them into the permanent structure of our mode of life. In the same way, advantage can be taken of the opportunity afforded by the crumbling of prejudice or privilege under the demands of war economy to make advances which in peace-time have long been delayed by vested interests. In the working out of new and dynamic conceptions of freedom and discipline, a final reply can be given to the totalitarian taunt of effete or decaying democracy.

The elaboration of a complete programme at the present time is both premature and undesirable. To arouse a general awareness of the opportunities, to stimulate a creative and adventurous outlook, so that in our thinking about immediate problems there is awareness and subconscious, if not deliberate, thought about the way in which they can be linked up with the post-war problems, is sufficient. If only this be done, a vital part of the preparation for further advance will have been carried out, the lack of which was a main hindrance after 1918. Without the adequate preparation of public opinion, the creation of a Ministry of Reconstruction by itself could achieve little. New forms of freedom will always be rejected until, as Mannheim points out, men have been prepared spiritually for them and ceased to think in terms of an earlier phase of social existence.

Reference has been made from time to time in these columns to some of the possibilities in regard to nutrition and health and the standard of living which might flow from a far-sighted food policy, embracing production, distribution and storage, agriculture and horticulture, initiated primarily to meet our war-time requirements. Another complex problem which should not be approached from the point of view of war effort alone is the most effective utilization of man-power in production and in the armed forces. The immense powers of the Minister of Labour and the Minister of Supply in regard to the control and dilution of labour, the utilization of skilled or professional labour of all kinds, the introduction of women and of part-time labour, the deflection of production and labour from non-essential industries, if wisely exercised in connexion with adequate short-term and long-term training policies, should make an important contribution to the solution of the unemployment problem.

This point is the central theme of a recent pamphlet "Post-War Poverty and Unemployment can be Prevented" by T. W. Wyatt and D. Caradog Jones (J. Woolman and Sons, Dacre Street, Birkenhead. 6*d*.). If economic depression and unemployment, can be temporarily cured by war, a better and more radical cure must be possible under conditions of peace. Pointing out that to all intents and purposes the War is being paid for as it is waged, that under war conditions money is not the essential consideration, and that the great mass of production and service utilized for war purposes is supplied in Great Britain, the authors argue that if the situation is properly handled by the Government, a repetition of the economic depression and serious unemployment which followed the War of 1914–18 is not inevitable. It should be possible, when peace comes, to change over from war production to peace production, and so make use of our vastly increased capacity for creating new wealth.

To utilize effectively the immense potential power of production, a carefully thought-out plan is essential, co-ordinating all forms of industrial activity. Messrs. Wyatt and Caradog Jones consider that their aims can be achieved under the present economic system, where private enterprise has free play, subject only to the appropriate Government control. Demobilization, for example, should be carried out gradually and systematically, and all who have given their service to the country should continue to receive full pay until they are absorbed again into industry. The aim of those directing affairs should be so to adjust spending, whether by taxation or rationing, that supply keeps step as nearly as possible with demand. If private enterprise proves insufficient within a reasonable time to absorb all demobilized men and women and to maintain consumption, public works should be instituted. There is no limit to work of this kind that might be done. Roads and transport, forestry, town- and country-planning, water supply, and electric power distribution provide innumerable opportunities, and no consideration of cost should interfere with the Government programme, provided only that the work undertaken is thoroughly and efficiently executed.

Discussing the possibility of inflation, Messrs. Wyatt and Jones believe that an expansion of currency for such purposes is safe until our resources of man-power and machinery are fully and adequately employed. They make the further point that in this new order we must school ourselves to a greater willingness to contribute gladly from our surplus income for social purposes. A planned economy is also essential because in due time it will be necessary to regulate the speed of production. The primary aim of the Government should be to adjust its financial policy so that an expanding market is always available for the goods produced. They further consider that by a systematic and continuous increase in production we can raise the standard of living all round.

To meet the new situation intelligent organization and administrative ability are the gifts which will be most in demand. Skilled workers will also be required for key positions; they may not be immediately available in sufficient numbers, and some may have to be trained. If, however, the problem is attacked on scientific lines and an honest attempt made to utilize fully the available resources, these needs can be met.

A constructive postscript to the pamphlet by J. R. Bellerby suggests that the post-War period will be marked by five fairly distinct phases. An initial phase of momentary depression is likely to be followed rapidly by one in which labour is fully employed in capital reconstruction, and Government action in this phase is of the utmost importance. The transformation of the Ministry of Supply into a Ministry of Reconstruction with specific powers to guarantee priority in the requisition of raw materials, machinery and services for the most vital consumptive goods, to control demobilization, adjust the flow of gratuity payments to the Forces, and postpone public or semi-public works, would be vital contributions. This phase would, if managed well, merge into a third phase in which there would be no serious shortage of essential consumable goods. In this stage an additional amount of deferred pay and gratuities to the Forces could be released. These three phases, throughout which the national budget is likely to remain unbalanced, would be followed by a fourth phase, characterized by a lack of consuming power, and at this stage the Government would have in reserve all the public and semi-public works it had been able to postpone. The real post-War test, however, would come at the fifth stage, when these schemes had been exhausted and the true remedy must lie in the unconventional and the costly. We have to learn the methods by which a controlled economy can be worked, and create a race of men and women as competent to administer British industry in the general interest as their grandfathers were to administer the other functions of the State.

We must, it is true, temper this note of optimism and hopeful view by the realization that there are still backward and recalcitrant elements in our midst. Even in regard to food, it is a damning indictment of the management of hospitals and other institutions, calling for immediate and drastic action, that the Ministry of Food should need even to issue a suggestion that the present abundant supplies of fresh fruit and vegetables should be used in place of drawing on reserves of canned supplies. Widespread uneasiness has also been caused by Mr. Bevin's recent disclosure in the House of Commons that some employers have failed to respond to his appeal regarding training of men at the higher and lower levels of skill. The reluctance of the Government to use its powers of compulsion has been the subject of as much criticism as its apparent absence of any clear policy in regard to the introduction and training of women, the industries or sources from which they are to be drawn and the equally important problem of utilizing on war work the labour compulsorily evacuated or transferred from defence areas.

These disturbing signs are evidence that one of our greatest tasks to-day is that of finding leadership of the requisite competence and integrity in politics, in industry, in finance, in art, in journalism, in the Civil Service. The raw material of leadership is as abundant as ever, but we can no longer claim that our social system is selecting and throwing up ability with the same outstanding efficiency and success as in the past. For this reason alone a thorough overhaul of our educational system is a vital necessity.

A prominent feature of the present situation is indeed that in general outlook the community is often far ahead of its leaders. In one field after another, in finance, in criticism of the budget or of labour, in the utilization of part-time services, alike for munitions production or in civil defence, the cry is that enough is not being demanded of us, insufficient guidance is being given, and inefficient use made of willing service. This feature has implications the importance of which can scarcely be overstressed.

In the planning to which we have referred we are in essence outlining a Bill of Human Rights embodying the minimum requirements for decent living, including the basic guarantees of the individual, such as freedom of speech, writing and religion, the right to a fair trial, the subordination of all government to the rule of law, the establishment of minimum standards of housing, food, education and medical care; and the provision of security against unemployment, accident, widowhood and old age. The presence of this widespread spirit of service in the community is one of the strongest safeguards against any undermining of the sense of individual social responsibility in the process, which Prof. Mannheim remarks must be carried out before planning can work smoothly, of abolishing the more blatant differences in wealth and opportunity.

It is of vital importance that this spirit of service should be canalized into some more permanent form. The counterpart to a Bill of Human Rights should be, as a recent leading article in *The Economist* has suggested, a Bill of the Duties which the citizen owes to the community of which he is a member. The minimum of rights will be the more cherished if it is paid for by a minimum of duties. Out of the fabric of relations involved in civil defence and the like, we may well evolve a new conception of the 'good neighbour'. We must now think of the community, the commonwealth, to which we give, from which we receive, of which we are all members, rather than of the State as an impersonal dispenser of free doles, or hard levier of taxes.

Here indeed is an ideal which should receive whole-hearted support. We are beginning to realize that we must plan the whole of our society and not merely parts of it, and that in planning parts we must have regard to the fate of the whole. We are learning individually to take a progressively longer view, and in the process the faculty of considered judgment is inculcated. Widespread evidence to-day shows that more and more men and women are becoming fit to share the responsibility for planning the whole course of events in the society in which they move.

MEDICAL SERVICE IN WAR

Organization, Strategy and Tactics of the Army Medical Services in War
By Lt.-Col. T. B. Nicholls. With Chapters by Air-Commodore A. S. Glynn, Col. A. R. Laurie and Col. F. G. Lescher. Second edition. Pp. xvi + 496. (London: Baillière, Tindall and Cox, 1940.) 15*s*.

IT is difficult, in these troublous and anxious days, to divert one's thoughts to any subject other than the ever-present War. Having listened to the wireless, read the daily paper and completed the daily duties, one desires to have mental relaxation with some form of light literature.

Consequently, when one takes up a book connected with the subject of war, one is rather prone to lay it aside with a feeling of distaste. The reviewer confesses that he experienced some such feeling when he recently took up the present volume written by Lieutenant-Colonel Nicholls with chapters by Air-Commodore Glynn and Colonel Laurie. First impressions are often fallacious and in this case proved to be markedly so. Having commenced to read the book, the chief difficulty was to put it down; one went on from page to page and, having attained the end of the final chapter, one's chief desire was to read the book again and grasp facts more thoroughly.

Tempora mutantur, nos et mutamur in illis; this is very certainly true with regard to the medical services of the Army. How vastly conditions have changed since the War of 1914–18. Changed in every way: mechanization of units, those of the medical services in common with other branches, new weapons, the immense increase in the air arm, the huge size of opposing forces, the speed with which they move and consequently the rapidly varying situation and the changing aspect of the battle from hour to hour. All these factors tend to an enormous increase in the number of casualties, and it is inevitable that the problems of collection, evacuation and treatment of the wounded are vastly more difficult than has ever previously been the case.

Another difficulty which presents itself in modern warfare is that a present-day campaign is not merely one of opposing military forces; the civilian populations have to be taken into consideration and the casualties among them may probably be very heavy. Coping with them, in addition to those of the fighting forces, will prove no easy matter.

Prior to the War of 1914–18 we were guided, in estimating the probable number of casualties, to a great extent by Cron's formula, but even then Cron's formula was found to be to a great extent fallacious and not to be relied upon, and this will be infinitely more so now. It is highly probable that, in the present War, we shall have to revise our ideas to an enormous extent.

The real essentials of successful medical organization in a modern campaign are elasticity, a power to appreciate rapidly changing situations, to make quick decisions and to acquire an ability to organize rapid—indeed instantaneous—improvization. The book under review brings these facts very forcibly to notice. The whole subject of evacuation from the front to the base is very thoroughly dealt with. The manifold duties of a regimental medical officer might perhaps have been more fully explained with advantage. Every battalion is not constantly in action and, important as are the duties of the regimental medical officer during actual fighting, yet during the periods of 'rest' (so-called) his duties are onerous and of great value to the unit to which he is attached.

It is laid down in Regulations that the first duty of the medical service is the preservation of health, the professional care of the sick and wounded coming second. While the actual responsibility for the preservation of the fitness of troops rests with the commander of those troops, it is the duty of the medical officer to watch matters carefully and to give judicious and timely advice to the commander as to what measures are advisable regarding preservation of health and how these measures had best be carried out. Such advice will be received and acted upon, in fact will frequently be eagerly solicited; the reverse is fortunately very much the exception.

If the regimental medical officer takes his duties really seriously, he will find that he is an extremely busy man even during a period of 'rest'. The closer the co-operation between the commander of a battalion, the adjutant and the medical officer, the better the health and fitness of the battalion will be.

The chapter on the casualty clearing station is very important and interesting; this unit is the first place in the line of evacuation in which actual hospital accommodation is provided and where full surgical treatment can be carried out. The casualty clearing station is really the pivot in the line of evacuation.

An extremely interesting section is that which deals with the transport of casualties by air and also with the many ways in which aircraft may be of inestimable service in the conveying of medical personnel, supplies, etc., both in peace-time and in war. A striking instance of this is that of the 'flying doctor' service in Northern Queensland and other parts of Australia. Anyone who is acquainted with this service is well aware of the untold benefits it has conferred on sick or injured people in out-of-the-way parts of the country. For example, a case of acute appendicitis may occur in an 'outback' station; the nearest surgeon is one hundred and fifty miles away, bad roads and flooded creeks intervening. A telephone message to the service headquarters will result in the very speedy advent of a surgeon, removal of the patient by aeroplane to hospital and operation, the whole procedure taking a few hours. Another example was furnished when the terrible earthquake occurred at Quetta a few years ago; a medical unit, a large number of medical officers and nurses, more than half a ton of medical stores and food, and about two tons of clothing were rapidly conveyed to Quetta by aeroplanes from Peshawar, Ambala, Karachi and other stations; the benefit was incalculable. These are but two examples of the value of the air service in medical work; the present War will doubtless furnish many more.

A point which has been wisely stressed is that of the precautions which are necessary with regard to the storage and use of radium in war-time. Naked radium might be liberated as a result of high-explosive action, and the consequent results might be extremely serious; the practical precautions which should be taken in order to avoid such risks are clearly and practically indicated.

Part IV is devoted to the "Emergency Medical Service". This section will be of very great value, not only to medical officers of the fighting services, but also to civilian medical men and women throughout the country. The present War is a 'peoples' war' and affects everyone; civilian casualties may quite possibly be immense in number and severity, and dealing with them will present a problem which will tax the resources of all medical and nursing personnel, civil and military. Casualties in bombed cities and towns will require rapid collection, treatment and removal to hospital; the selection of the most suitable site for a 'casualty hospital' for such cases will be no easy matter. Trueta, who had very considerable experience of air raids in Barcelona and elsewhere, points out that these hospitals are often from necessity in a vulnerable area, and perhaps the safest are those in districts with modern anti-aircraft defences, such as balloon barrages, anti-aircraft guns, etc.

This book which we have been considering has been written by Army men for Army men, and the information which it contains should conduce to the efficient medical treatment and welfare of the soldier. Presumably the present War will be followed, as was the last, by a spate of post-War literature. After the War of 1914–18, many books of reminiscences and numerous novels were written; some of these were of real interest and presented a true picture of the lives of officers and soldiers in war-time. Other books (fortunately in the minority) were simply abominable and portrayed the British soldier in utterly false colours. The present reviewer, in setting forth his very definite and positive views regarding the British soldier, feels quite satisfied that he is stating nothing but the simple unvarnished truth—truth which nobody with real knowledge can controvert—and his opinions are the result of a life-time's experience. The term 'British soldier' does not here refer only to the men of these islands; it is intended to include soldiers of the British Commonwealth all over the world—Canadians, Australians, New Zealanders, South Africans, Indians and many others. With all of these the reviewer has served, he has worked with them and played with them, and without a shadow of doubt or hesitation he feels most strongly that there are no finer men in the whole world than the fighting men of our Empire, brave, cheery, patient in suffering, steadfast in adversity, loyal and big-hearted.

Such men deserve the very best we can give them and the very utmost we can do for them. Believing all this, the reviewer cannot but feel deeply resentful and angry when he reads articles or books in which the soldier is sneered at or vilified by authors who probably have but little real knowledge or experience of him, who do not understand his life, his trials, hardships and suffering, and who themselves could scarcely hope to attain to his standard of courage, endurance and self-sacrifice.

Few branches of the Army have the privilege and honour of being able to do more for the welfare of the rank and file than have the Army Medical Service; this Service has done much for the soldier in the past and will do even more in the future. It is evident that the writers of the book under review have the interests of the British soldier at heart; it is also very evident that they have studied carefully the many and difficult problems of medical organization and administration in war. The book is the result of hard work and careful study, and will be of great assistance not only to officers of the medical service of the Army, but also to the many thousands of physicians and surgeons who in the onerous days ahead will be engaged in war work.

HISTORY AND SCIENCE

History and Science
A Study of the Relation of Historical and Theoretical Knowledge. By Hugh Miller. Pp. xi+ 201. (Berkeley, Calif.: University of California Press; London: Cambridge University Press, 1939.) 12*s*. net.

THIS is a valuable and interesting, though somewhat difficult, book of which the avowed purpose, as we are told on the cover, is to "free empirical science from the ghosts of the rationalistic past which still haunt and mislead its progress". It is well worth reading for the variety of thoughts which it expresses, although one is bound to say at the end that the solution offered is not as clear as the apprehension of the difficulties which surround its approach.

The author explains his theme in a short biographical introduction in which he says that from the earliest years he has been perplexed by the opposition of the two sorts of thinking which are constantly presented to our minds; one he calls theoretical science and the other historical science. (One must note, by the way, that his habitual use of the word 'theoretical' in this restricted sense rather adds to the difficulty of reading his book.) But the main gist and purpose are clear enough. We have on one side a body, let us say, of conclusions or doctrines of which mathematics seems to be the most perfect, which stand firm and rise above the tide of historical change. Thus the equality of two and two to four is apparently a fixed and unalterable truth (the author would say a 'theory'). On the other side we have the constantly changing facts of organic life, of which he ascribes the discovery rather too exclusively to Darwin. Man is the highest product of these, and we have to assume that the mind of man which is his highest—or at least most peculiar—feature has also changed through the ages. How then are we to reconcile the eternity and permanence of what he calls "theoretical science" with the infinite change and growth of the organic side of the universe which is best represented to us in man? It is a pretty problem, and Prof. Hugh Miller follows it through three books and twelve chapters with great persistency and a good deal of enlightenment. He cites numerous philosophers from the earlier Greeks down to Bergson and, if it were not for a confession of faith in the preface, one would be inclined to say that the historical or changeful side of thought wins all the way. In fact the closing words of the last chapter are a moving appeal to history. "Action is our last honesty. Let us act—we have surmised enough—and show what our hearts are bent upon. Let us allow the appeal to history and in the name of history, fight".

This appeal goes home to the heart of the present reviewer, who has always held that history—especially the history of science—was the most important part of intellectual progress and should be made a leading feature in our educational courses. Science has grown and is constantly changing and we—outside Nazi Germany—are trying to keep pace with it. In that sense above all we would echo the eloquent epilogue of Prof. Miller and "in the name of history, fight".

Yet one cannot turn one's back on all the great conclusions of the thinkers of the past; one must still believe that two and two make four, even though our earliest ancestor may have thought the same thing. The answer to the whole dilemma is clearly a compromise, as the author indicates in his preface. There are certain constant structures of fact and thought which stand firm throughout the evolutionary process. Just as every animal form needs some food to sustain it, so it is constantly true that two and two make four. On these and a good many other permanent truths the mind feeds and grows.

We have in the present state of knowledge a long perspective of the past evolution of life which has given us an entirely new orientation towards history. All life is history, and this historical life has from the first and throughout a basis of non-evolutionary science. The living side now includes geology; it cannot be said to include either physics or astronomy, although we are always on the track of some evolutionary explanation of the heavenly bodies. Mathematics, however, in its foundations appears unaffected by the changes of organic life. Man discovers transcendental numbers but he does not create them. The mathematical foundation of our universe of knowledge appears to come from a distinct source from that of life. Is it—as Sir James Jeans has suggested—that God, as the mathematician, has working with him a co-adjutor or another side of His being which comes to its highest force in men's minds? The mathematical foundations remain secure while life develops in infinite richness of variety.

It is these and similar thrilling questions which Prof. Hugh Miller raises in his thoughtful book.

F. S. MARVIN.

ANIMAL BEHAVIOUR

(1) Die tierischen Instinkte und ihr Umbau durch Erfahrung

Eine Einführung in die allgemeine Tierpsychologie. Von J. A. Bierens de Haan. Pp. xi + 478. (Leiden: E. J. Brill, Ltd., 1940.) 8 guilders.

(2) Animal Behaviour

Impulse, Intelligence, Instinct. By Dr. Johann A. Loeser. Pp. x + 178. (London: Macmillan and Co., Ltd., 1940.) 10*s.* 6*d.* net.

(1) DR. BIERENS DE HAAN'S book is well described by its extended title; it surveys the whole field of instinctive behaviour and its modification through learning, and constitutes an admirable introduction to the study of animal psychology. It is, as the author claims, the first general treatise on animal behaviour to be written from a purely psychological point of view. Dr. Bierens de Haan holds that the true science of animal psychology begins where behaviourism in its various forms leaves off; the facts of behaviour require interpretation in terms of the animal's subjective experience, in terms of knowing, striving and feeling, at least in their elementary forms. That instinctive behaviour is rooted in life, and cannot be understood without reference to the normal ecological conditions of the species the author freely admits; but he has concentrated his attention mainly on the psychological aspects of animal behaviour. That is the special key-note of the book. It is appropriately dedicated to the late Prof. Wm. McDougall, whose hormic point of view he shares.

Dr. Bierens de Haan, whose laboratory is in the Zoological Gardens at Amsterdam, is, of course, well known in Great Britain as a leading worker in the field of animal psychology, and he has made us all his debtors in providing this up-to-date survey of the subject. Great progress has been made of recent years, especially on the Continent, in the study of animal behaviour, and there is real need for a book like this which brings the facts together and indicates what they mean. With its full bibliography of thirty-five pages, and its three indexes, the book will be extremely useful, and indeed indispensable, to the serious student, and must find a place in his library.

A good half of the book deals with instinctive behaviour, and especially the simpler forms of it, which the physiologically minded call taxes and tropisms. While no attempt is made to cover the whole immense field, the numerous examples chosen from the modern work on the subject are highly interesting and instructive, and there is no better treatment of the general subject extant.

Like McDougall, Bierens de Haan draws a distinction between instinct and instinctive behaviour, defining the first in purely psychological terms. His definition (p. 34) closely resembles the well-known one proposed by McDougall—"an inherited or innate psycho-physical disposition which determines its possessor to perceive, and to pay attention to, objects of a certain class, to experience an emotional excitement of a particular quality upon perceiving such an object, and to act in regard to it in a particular manner, or, at least, to experience an impulse to such action". Bierens de Haan's definition is somewhat fuller, and brings out the important point that specific perceptions and feelings may also be aroused by specific drives. While instinct is a purely psychological activity, instinctive behaviour is also a biological phenomenon, showing characteristics which require definition in biological terms. In particular, instinctive behaviour is usually purposive in a biological, but not in a psychological, sense—the animal acts instinctively, in normal conditions, in a biologically adequate way, but without knowledge of the end pursued; it "knows how" to act, but not why it acts; as Spaier has well said, it shows "savoir-faire" but not "connaissance".

In the second part of the book, the effect of experience and learning in modifying behaviour is fully and adequately discussed, in the light of modern work and the author's own extensive researches in this field. Here the important point is made that the role of learning and intelligence is secondary, that the instincts remain the essential factors in behaviour, though extended, modified and illumined by intelligence, Special attention is given to the higher forms of animal intelligence, where the animal shows what Bierens de Haan describes as a "concrete understanding" of spatial and causal relations.

(2) Dr. Loeser's book falls into a different class. In it he gives expression, in a popular way, to a particular view about instinct, which he published in a more technical form in 1931 (not 1939, as stated in the foreword) under the title "Die psychologische Autonomie des organischen Handelns". The circumstances in which this English version came to be issued are sympathetically explained in the foreword by Mr. L. J. F. Brimble, who has well carried out the arduous

task of preparing the book for publication after the tragic death of the author while a refugee in Great Britain.

Dr. Loeser would have us give up the notion of instinct altogether, and substitute for it that of small voluntary acts, strung upon a base of biological purposiveness or adaptedness, which he assumes to be given by the physical constitution of the animal. "Each 'instinct'," he writes, "such as bird migration, the honeycomb-building of the social Hymenoptera or their complicated system of caring for their young, can be divided up into a number of 'small' voluntary actions. These 'small actions', combined with a specific physical constitution, which becomes effective in the animal's natural surroundings, unite to produce *one* biologically purposive action" (p. 174). There is no rigid and automatic connexion between impulse and reaction ; in any given situation the animal does the best it can, according to the "pleasure principle". From this point of view Loeser attempts to explain, or explain away, many of the classical examples of instinctive behaviour, as, for example, nest-building in birds' migration, egg-laying and care of young. Most people will find his interpretations rather far-fetched and unconvincing. In biological matters he is not a wholly reliable guide ; there are too many sweeping general statements of doubtful accuracy. He writes as a psychologist, and is not free on occasions from the error of anthropomorphism.

The book has, however, its merits, and it deserves to be read for the unconventional and provocative nature of the views expressed. Loeser is undoubtedly right in emphasizing the psychological character of instinctive behaviour, in refusing to treat such behaviour as mechanistic or rigidly determined ; he is right also in stressing the simplicity and proneness to error of the psychological processes involved ; but he fails to see that the biological adaptedness or purposiveness of instinctive behaviour lies in the instinctive impulses themselves, as part of the inherited psycho-physical constitution of the animal.

POTASSIUM COMPOUNDS

Gmelin's Handbuch der anorganischen Chemie
Achte vollig neu bearbeitete Auflage. Herausgegeben von der Deutschen Chemischen Gesellschaft. System-Nummer 22 : Kalium, Lief. 6, Schluss der Verbindung. Pp. 1075–1230. 21–75 gold marks. Lief. 7 : Techniche Darstelling der Kalisalze. Pp. 1231–1338. 16.50 gold marks. (Berlin : Verlag Chemie, G.m.b.H., 1938–39.)

PART 6 of the volume on potassium in "Gmelin's Handbuch" terminates the account of its compounds and deals chiefly with such compounds as contain also either lithium or sodium. Whereas the chlorides of lithium and potassium give merely a eutectic mixture, the system between the two sulphates is complicated by the fact that each of the two latter is dimorphous. A liquid alloy of sodium and potassium was known to Sir Humphry Davy. The compound NaK has not been isolated, but its existence is inferred from its band spectrum. It is chemically more active than either of the two metals.

Phase-rule studies of various combinations of salts of potassium and sodium, including the tartrate, are described. Particular attention is devoted to Rochelle salt on account of its remarkable properties, the most outstanding of which are its marked piezo-electric effect and the anomalous dielectric properties in the direction of the crystallographic a-axis. The two properties are closely inter-related, but the anomalies disappear not only above 24° C. but also below $-18°$ C.

Part 7 contains details of technical processes in the production of potassium salts. It is just a hundred years since boring was first undertaken at Stassfurt with the object of finding the origin of certain natural brine supplies. The importance of the rock salt which was discovered was not at first realized owing to the presence in it of 'undesirable' potassium and magnesium salts, and many years elapsed before the potash industry was established. A three-page table shows the gradual development of the industry in various countries between 1861 and 1936.

After the War of 1914–18 the important deposits in Alsace passed into the possession of France and other sources have been discovered in Poland, Spain and America. An international agreement was reached in 1925 for the regulation of production and supplies. An account is also given of many other technical processes such as the extraction of potassium salts from seaweed, from sea water and from the waters of certain inland seas, and of the separation of potassium chloride from carnallite and also of potassium salts from borax.

THE BUSH DIFFERENTIAL ANALYSER AND ITS APPLICATIONS*

By Prof. D. R. Hartree, F.R.S.,
University of Manchester

IN the application of mathematics to problems both of pure and applied science, there often arise differential equations which have no formal solution, or none convenient for numerical evaluation, but for which numerical values of the solutions are required. Though there are numerical methods of dealing with such situations, it would often be advantageous, as an alternative, to have mechanical means of evaluating solutions of differential equations, and this is the purpose of the 'differential analyser' of Dr. V. Bush, of the Massachusetts Institute of Technology.

Fig. 1.

General view of differential analyser at the University of Manchester. Photo by Metropolitan-Vickers Electric Co. Ltd.

The general idea of a machine for evaluating the solutions of differential equations is not new. Integrating mechanisms have been known for more than a hundred years, and the idea of connecting several such mechanisms together, in such a way that the combination of them would evaluate solutions of differential equations, was stated clearly by Kelvin[1] in 1876. But the whole credit for designing a machine which could be constructed in practice, and which would work accurately when built, must be given to Dr. V. Bush and his team at the Massachusetts Institute of Technology, where the first such machine was built about ten years ago[2]. The first machine of this kind in operation outside the United States was the one, with which I have been closely connected, at the University of Manchester (Fig. 1). This machine was built by the Metropolitan-Vickers Electrical Co., Ltd., and I must acknowledge the generosity of the late Sir Robert McDougall, who defrayed the cost of the machine to the University, and the friendly help I have had from Dr. Bush himself and from Dr. A. P. M. Fleming and all those members of the Research Department of Metropolitan-Vickers who have been engaged on its design, construction, installation and maintenance. Without the help, in various forms, which I have had from these sources, the installation of this machine would not have been possible. Through the interest of Prof. J. E. Lennard-Jones a second such machine, also built by Metropolitan-Vickers and including improvements in detail suggested by our experience at Manchester, is in operation also in this country, at Cambridge. There are now, so far as I know, altogether seven or eight full-size machines in operation in the world. There are also, in Great Britain, several smaller and less accurate model versions of the machine, of which the first was built, originally for demonstration and instruction purposes, by Dr. A. Porter and myself[3].

---

* From a Friday evening discourse at the Royal Institution delivered on May 17.

GENERAL IDEA OF DIFFERENTIAL ANALYSER

The differential analyser consists of a number of units, each of which can carry out one of the operations which may be involved in the mechanical solution of a differential equation. The essential units are the integrating mechanisms, each of which is a precision form of continuously variable gear. There are eight of these, in cases in pairs (Fig. 1, *A*). These can be interconnected in various ways, either directly or through other units of the machine, by shafts and gearing. There are two sets of shafts; cross-shafts driving or driven by the various units of the machine, and longitudinal shafts by which connexions are made between different units. Each shaft represents one of the quantities occurring in the equation; the rotation of the shaft measures, on a chosen scale, the magnitude of that quantity.

It is often necessary to supply to the machine information concerning a relation between two of the quantities occurring in the equation under investigation; for example, in calculating the scattering of electrons by an atom, it is necessary to supply the machine with the relation between the potential of the atomic field and the distance from the centre of the atom. This is done from an input table (Fig. 1, *C*), of which there are six. A graph, expressing the relation to be supplied to the machine, is drawn beforehand and placed on one of the tables, and is followed by an operator as the solution proceeds.

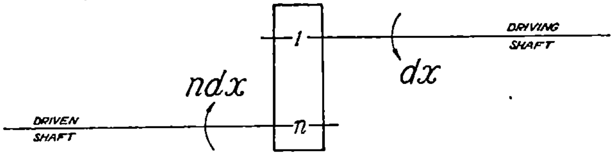

Fig. 2.

CONTINUOUSLY VARIABLE GEAR AS INTEGRATOR.

There are also means of recording the solution either in the form of a graph on an output table (Fig. 1, *B*), or numerically by recording the readings of a set of revolution counters (Fig. 1, *E*).

INTEGRATORS

Any continuously variable gear will serve as an integrating mechanism (Fig. 2). Let a driving and driven shaft be connected by any mechanism such that the driven shaft runs n times as fast as the driving shaft; then for a small rotation dx of the driving shaft, the rotation of the driven shaft is ndx, so that if the gear ratio n is varying as the driving shaft is rotating, the total rotation of the driven shaft is $\int ndx$. For the present purpose we require a form of continuously variable gear which can be set accurately to any gear ratio n within its range, and this range must include zero and negative values of n without any mechanical difficulty. A convenient form (Fig. 3) consists of a wheel the plane of which is fixed, driven by the rotation of a disk of which the axis is carried in a carriage so that the distance of the wheel from the centre of the disk can be varied. Alteration of this distance alters the gear ratio between the shaft driving the disk and that driven by the wheel, and the gear ratio is proportional to the displacement of the disk from its central position.

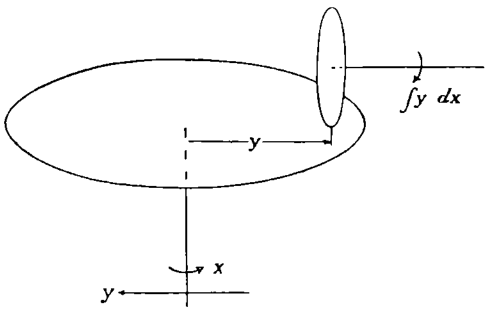

Fig. 3.

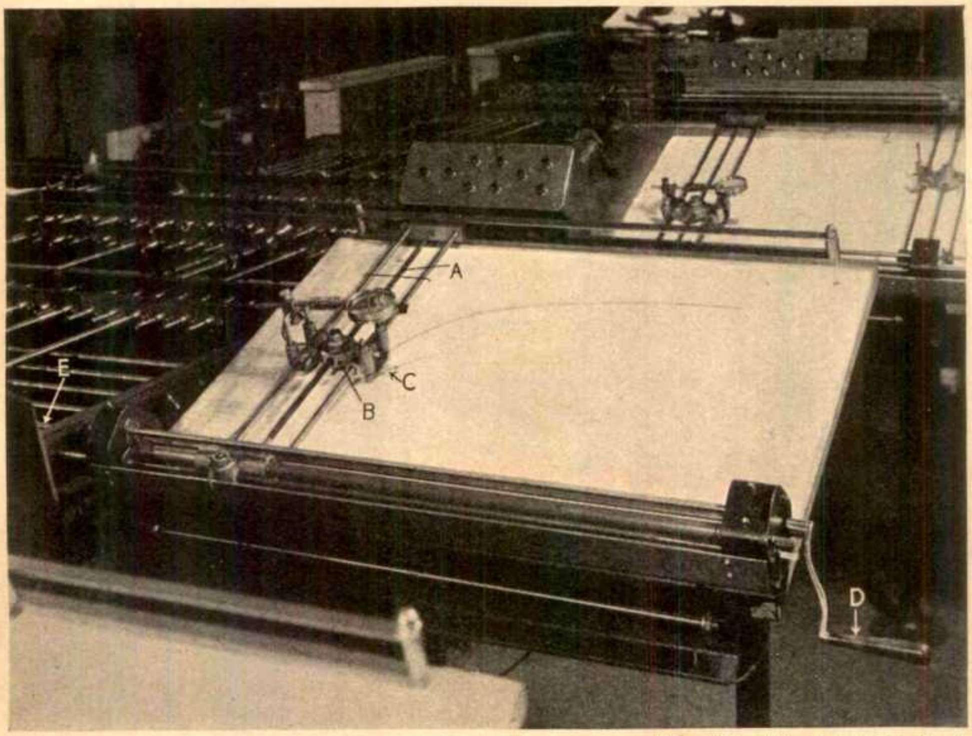
PRINCIPLE OF THE INTEGRATOR.

Each integrator is provided with a servo mechanism, by which the driven shaft is made to rotate at the same speed as the integrating wheel, but with greatly increased turning force or 'torque', whence the name 'torque amplifier'. The principle in which this operates is much the same as that of the capstan. The shaft carrying the integrating wheel and the shaft to be driven are fitted with arms, which are connected by bands running over two drums driven in opposite directions by a motor. When the integrating wheel starts to turn, one band tightens and the other loosens; the tightening of the one band increases the friction between it and drum; this tightens it further, so that the tension builds up exponentially along the band, and the driven shaft is pulled round with a much greater force than that applied by the input arm. In effect, the rotation of the integrating wheel does not directly drive the output shaft, but controls the supply of power to it from the motor driving the torque amplifier drums.

INPUT AND OUTPUT TABLES

Each input table (Fig. 4) consists of a bridge (*A*) spanning the table, the bridge being movable perpendicular to its length and supporting a carriage (*B*) which can be moved along it by the rotation of a handle (*D*), and the carriage carries a pointer (*C*). The table carries a graph, drawn beforehand, expressing the information to be fed to the machine. The bridge is moved along the table by the operation of the machine, and as it moves over the graph, an operator turns the handle so as to keep the pointer on the curve. The handle also drives one of the cross shafts (*E*) of the machine, from which the information expressed by the graph can be fed into the machine wherever required. It is possible to replace the human operator by an automatic curve follower operated by a photo-cell; one such has been built by Hazen[4] at the Massachusetts Institute of Technology, and another working on a different principle suggested by Blackett and developed by F. C. Williams[5] has been tried successfully in an experimental form at Manchester.

Occasionally, if a quantity is varying with time, its rate of change at any moment may depend not only on its value at that moment, but also on the value it had at some previous time. To deal with such a situation a special input table can be used; this has two bridges, one carrying a pencil and the other a pointer. Both bridges move along the table, with an interval between the pencil and pointer. The pencil draws a curve and after an interval the information expressed by this curve is fed back to the machine by an operator who keeps the pointer on the curve already drawn by the pencil. This unit (Fig. 1, *D*) was first developed at Manchester in connexion with some work on the effect of time lag on automatic temperature control in industrial plant[6].



[*By courtesy of the Mathematical Gazette*

Fig. 4.

INPUT TABLE. PHOTO BY METROPOLITAN-VICKERS ELECTRIC CO. LTD.

The output table is similar to an input table, but in place of the pointer of an input table which is kept on a curve by an operator, there are two pencils which are moved along the bridge by the machine, so that graphs of two quantities occurring in the equation can be recorded simultaneously. Sometimes such a graphical record of the solution is the most convenient form of result, but when accurate numerical values are required, it is better to record the results directly in numerical form. This can be done by having a set of counters driven by the machine, and recording their readings either by a printing mechanism or photographically by a camera (Fig. 1, *F*).

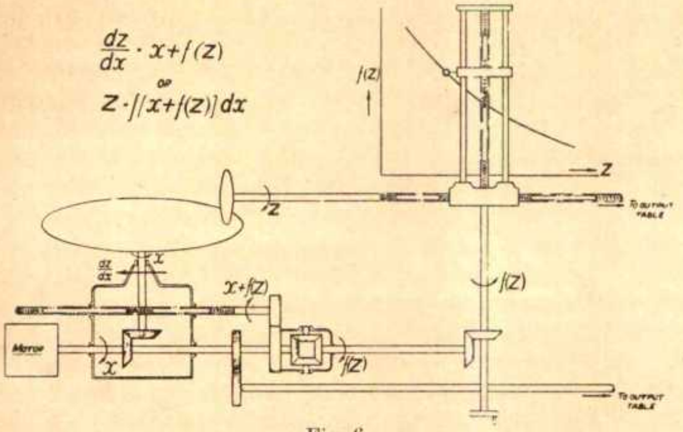

Fig. 6.

APPLICATION OF INTEGRATOR TO A SIMPLE EQUATION.

OTHER UNITS

There are various accessory mechanisms: adding units each of which is similar to the differential gear of a motor-car, epicyclic gear trains for compensating backlash which are therefore called 'frontlash' units, and gear wheels for connecting the various shafts. The longitudinal and cross-shafts are connected by cross-drives, each formed by a pair of helical gear wheels. By these, any longitudinal shaft can be connected to any cross-shaft. The great variety of different inter-connexions of the units of the machine thus made possible is the secret of the very wide range of equations to which it can be applied.

SMALL-SCALE MODELS

The first photographs I saw of Dr. Bush's machine gave me the feeling that someone had been enjoying himself with a super-Meccano set, and this gave me the idea of trying to build, so far as possible from standard Meccano parts, a model to illustrate the principles of the machine.

This was originally done more for amusement than with any serious purpose, but the first results were successful beyond my expectations, and suggested that it would be practicable to build such a model to do serious work on problems for which high accuracy was not required in the results. Largely with the help of Dr. Porter, such a model was built, and proved successful for such work[3] (Fig. 5). It has also been useful for demonstration purposes, for trying in an experimental form new ideas such as the special input table.

USE OF THE MACHINE

As already explained, the quantities occurring in the equation are represented by the rotation of various shafts. These shafts have to be connected, through integrators and other units of the machine, so that the relation between their rotations is a translation into mechanical terms of the equation to be solved.

Consider, for example, the equation

$$\frac{dz}{dx} = x + f(z)$$

(Fig. 6). To see how the machine handles an equation, it is often best formally to integrate once, which in this case gives

$$z = \int [x + f(z)]\, dx.$$

This shows that, at any value of x, the integrand (that is to say, the displacement of the integrator) is made up of two contributions, one x itself, and the other depending in a definite way on the value which the integral z itself has reached. Suppose we can supply the integrator with such a displacement (how this is done will appear shortly) and suppose we rotate it by a drive from the shaft whose rotation represents x. Then the rotation of the integrating wheel will be z. Let a drive from this wheel be taken to displace the bridge of an input table on which is placed a graph of $f(z)$ against z. If an operator (or automatic curve follower) keeps a pointer on the curve, the rotation of the shaft driving the pointer measures the value of $f(z)$ (on a suitable scale and from a suitable zero). If we take a drive from this shaft and one from the x-shaft to an adding unit, the output from the adding unit will be $x + f(z)$, and this is just what we want to furnish to the integrator as a displacement. Thus if the adding unit is connected up to displace the integrator, then the rotation of the x-shaft, which is driven by a motor, will drive the rest of the mechanism in accordance with the equation. (The 'mechanism' here includes the operator who follows the curve.)

APPLICATIONS

This differential analyser handles a mathematical situation, namely, that expressed by a differential equation, without reference to the particular scientific or technical problem from which that situation arises. Such a situation does arise very frequently and in a very wide range of problems, and the range of application of the machine is correspondingly wide.

It has been applied[7] to calculations concerning: (1) Structure and some properties of atoms, molecules, and atomic nuclei; (2) at the other end of the scale of size, on structure and stability of stars; (3) paths of electrified particles in the field of a magnet (aurora and cosmic rays); (4) energy exchange between a gas and a solid; (5) some examples of fluid flow round solid bodies; (6) potential distributions in cylindrical valves, both of steady-state and for rapidly varying conditions; (7) a number of examples of currents in electrical circuits, and on transmission lines, involving elements with non-linear characteristics or time-varying impedances; (8) starting characteristics of synchronous motors; (9) effect of time lag on automatic control systems; (10) train running times; (11) temperature rise and distribution in insulating material in alternating fields.

In conclusion, there is one thing I want to emphasize about the differential analyser, namely this, that despite its range and its capabilities, it is no substitute for a study of the formal mathematical theory of differential equations. Necessarily it can only evaluate particular solutions of particular equations; whereas if a formal solution is available, it will usually give the general solution of a whole class of equations, which is much more extensive, and often much more useful, information. The differential analyser is only to be regarded as a last resort when the formal theory gives no useful results. But so often in practical problems the last resort is the only resort, and it is then that the machine shows its scope and power.

EVOLUTION OF THE GALAPAGOS FINCHES

By DAVID LACK,
DARTINGTON HALL, TOTNES

INTRODUCTION

THE land faunas of oceanic islands have always excited considerable evolutionary speculation, and, starting with the "Origin of Species", the Geospizinæ, the endemic Galapagos finches, have probably featured in as many evolutionary discussions as any group of animals. They differ from almost all other land birds of oceanic islands in that there is more than one species on each island. Further, some of the species seem to grade into each other, and others are linked by freak specimens. Some workers have supposed that some quite peculiar method of evolution must have been involved.

Assisted by grants from the Royal and Zoological Societies of London, I spent December 1938–April 1939 on the Galapagos investigating the breeding behaviour and ecology of the Geospizinæ, following this with a statistical study of museum material. Another object, to interbreed the different species, failed on the islands, but is being continued with captive birds brought to the California Academy of Sciences, San Francisco. The following is a brief summary of some general evolutionary problems. Full results will be published later[1] together with a list of the many persons who helped the expedition, the museum study, and in discussion.

SUBSPECIES

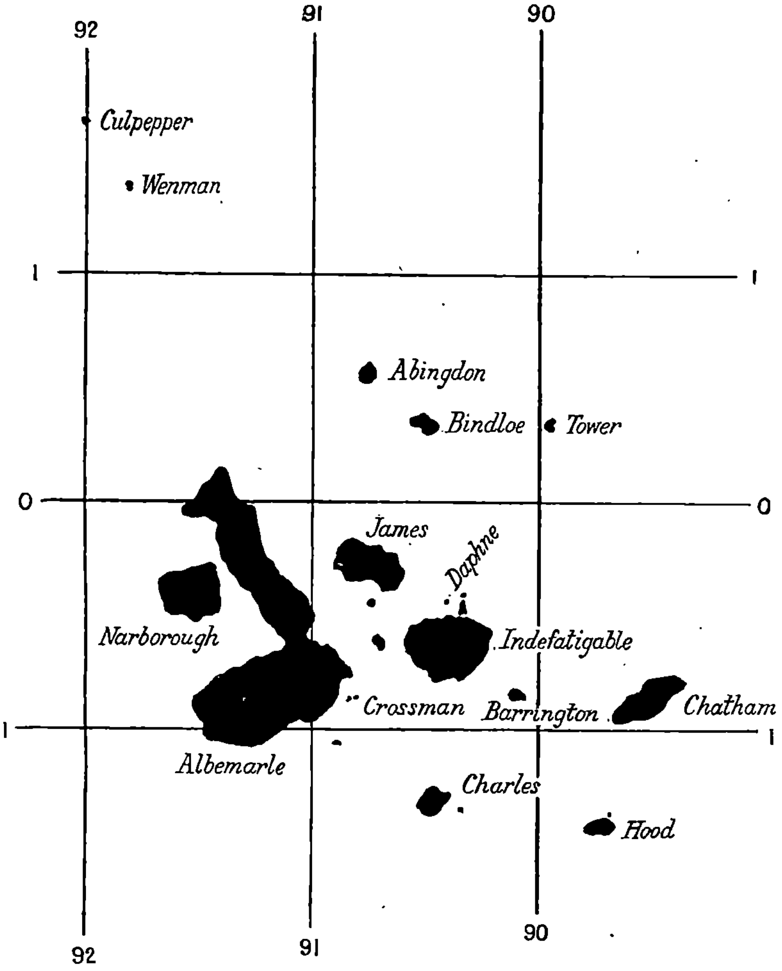
There are ten main species, each found on most of the islands. Some are divided into island subspecies, which differ mainly in beak size and minor plumage characters. The various Galapagos Islands present similar conditions for Geospizinæ, and no species show regular or parallel trends of variation on different islands. Hence I consider that isolation of small island populations has led to non-adaptive differentiation in the manner postulated by Sewall Wright[2]. That the two main factors in the formation of island subspecies are (1) degree of isolation (2) size of population, is indicated by the fact that small isolated islands have a higher proportion of endemic forms (also a smaller total of species) than have either small central islands or large isolated islands. Large isolated islands have a higher proportion of endemic forms than the central islands, large or small. Another point, the two most variable species, *Geospiza magnirostris* and *G. fortis*, are significantly less variable in three measured characters (namely, wing, culmen from nostril and depth of beak) on small isolated islands than they are on large or central islands. (This relation did not hold in four other less variable species.)

SPECIES

Geospiza magnirostris (large), *G. fortis* (medium size) and *G. fuliginosa* (small) are three closely related species which do not differ at all in plumage but solely in size and relative size of beak, and to some extent in song. The beak is the chief specific character, the larger species having relatively larger beaks. There is no allometric relation between beak and body size within each species, but the ratio is too subject to individual variation to form a reliable specific character. These three species occur together in the same habitat on many islands, the food and feeding habits of the first two seem identical, and of *G. fuliginosa* closely similar, and they use similar nest sites. On some, but not all, islands *G. fortis* is so variable that the smallest individuals appear more like large *G. fuliginosa* than like the largest individuals of their own species, and the latter appear more like small *G. magnirostris* than like the smallest individuals of their own species. (There is no evidence for selective mating by body and beak size within *G. fortis*.) Yet normally the three species keep distinct, and on most islands there is no evidence for hybridization, though this cannot be completely ruled out. There is a small overlap between the species in all characters, but nearly all specimens can be safely identified. However, a few specimens are intermediate in several characters together and cannot be safely allocated.

Field study showed no adaptive significance for the inter-specific beak differences *except* that they are the major (but probably not the sole) factor in specific recognition. A male usually attacks a rival by gripping its beak; frequently a male started to chase a member of a different species from behind, but usually, though not always, it stopped on coming round in front where its beak was visible. Experiments with wild birds which attacked and courted stuffed specimens confirmed the use of the beak in specific recognition.

Camarhynchus psittacula (large) and *C. parvulus* (small) occur together on most islands and present a similar problem to the Geospiza species, while on one island occurs a third species, *C. pauper*, differing from *C. psittacula* solely in a smaller depth of beak and in minor plumage details. In general, the closely related species of Geospizinæ are not usually separated by habitat, nest site, breeding season or any other geological factor. Geneticists seem agreed that isolation promotes inter-sterility, and I consider that these species have evolved via geographically isolated subspecies which later met on the same island and did not interbreed. The species differ from each other in the same characters which distinguish island subspecies, that is, in beak and sometimes in minor plumage characters. When beak differences assist in specific recognition, they will be intensified by selection quite apart from their relation to feeding habits, since hybridization is at a selective disadvantage. It is extremely difficult to see any other significance for the specific beak differences, or to understand why, otherwise, they should persist. But the highly variable *G. fortis* still presents great difficulties in interpretation.



The Galapagos Islands.

In two cases, the origin of a species via a geographical form seems clear. The *Camarhynchus psittacula* group is represented by one form on each main island except on Charles where two occur, *C. psittacula* and *C. pauper*. *C. pauper* was probably derived from the *psittacula* group via the form *affinis* on Albemarle to the west, as they are rather similar. *C. psittacula* on Charles is almost indistinguishable from *C. psittacula* on Indefatigable to the north, and probably colonized Charles from Indefatigable more recently, met *C. pauper* but kept distinct. Again, *G. fuliginosa* occurs on all the main Galapagos Islands except Tower in the north-east, where a rather similar species *G. difficilis* (formerly *acutirostris*) is found, which could have been derived from *G. fuliginosa* from Chatham to the south, and would probably have been classified as a subspecies of *fuliginosa*, but that it also occurs on Abingdon, to the west of Tower, together with a small form of *G. fuliginosa*, from which it keeps segregated.

Rensch[3] considers that, in general, most bird species have evolved via geographically isolated subspecies.

HYBRIDIZATION

Lowe[4] regarded hybridization as the main factor in species-formation in the Geospizinæ. The amount of hybridization has been greatly exaggerated. We saw no certain cases in the field. The occasional freak and intermediate specimens are not necessarily hybrids, and in any event have probably played little, if any, part in speciation. Hybridization may sometimes have occurred between two differentiated island subspecies of the same species which later met on the same island, but this is much more likely to result in a variable form of the same species than in a new species. However, in two cases a species-hybrid seems to have become established. On Culpepper in the extreme north occurs the highly variable *Geospiza conirostris darwini*, which shares characters of *G. magnirostris* (widespread on other islands) and *G. conirostris propinqua* (on Tower) and is probably of hybrid origin between these two. On the tiny islets of Daphne and Crossman (which are not near each other) occurs a highly variable Geospiza species intermediate in characters between *G. fortis* and

G. fuliginosa, and overlapping with both. Presumably it is of hybrid origin ; if so, here is the unusual case of two species which occur together over most of their range without interbreeding but which interbreed in two small isolated localities.

ADAPTIVE RADIATION

Island forms differ in non-adaptive characters and give rise to species which differ mainly in non-adaptive characters except in so far as these are recognitional. But, at a later stage, pronounced adaptive characters appear, and the main genera of Geospizinæ represent a minor adaptive radiation. *Geospiza scandens* is at an intermediate stage. It uses its long thin beak for feeding in Opuntia flowers, but these are seasonal, and much of its diet resembles that of other Geospiza species, which have finch-like beaks and eat mainly seeds. *Platyspiza crassirostris* eats mainly leaves. Camarhynchus species have beaks rather similar to Platyspiza, but eat mainly insects. *Cactospiza pallida*, clearly derived from Camarhynchus, has evolved in the direction of a woodpecker in both habits and beak. It also has the unique habit of holding a small twig or Opuntia spine lengthwise in its beak and probing insects out of cracks in trees, dropping this tool to seize the insect as it emerges. *Certhidea olivacea* is like a warbler in both beak and feeding habits. Despite their dissimilar feeding habits and appearance, all these forms have extremely similar breeding behaviour, which confirms previous anatomical findings as to their close relationship to each other.

EVOLUTIONARY FACTORS

The three main factors in the evolution of the Geospizinæ have probably been : (1) The almost complete absence of food competitors. A few other land birds now frequent the islands, but all except Nesomimus are so little differentiated from mainland forms that they probably colonized long after the ancestral Geospizid arrived. (2) The almost complete absence of predators. Worthington[5] shows the marked inhibitory influence of predators on adaptive radiation.

These two factors result from the extreme isolation of the Galapagos and the difficulty of colonization for birds. Both must diminish the intensity of selection.

(3) Equally important, the opportunities for temporary isolation of different forms provided by the existence of a number of islands. One species of Geospizid, *Pinaroloxias inornata*, occurs outside the Galapagos, on the extremely isolated island of Cocos, and is so differentiated that it has clearly been isolated a long time, but there is only one island and still only one species of Geospizid. In general, no bird groups have evolved similarly to the Geospizinæ on solitary islands, however isolated, but two parallel cases occur in isolated archipelagos. The two species of endemic finch, Nesospiza, in the Tristan da Cunha Islands differ primarily in beak[6], so here is Galapagos in miniature, and at the other extreme is the marvellous adaptive radiation of the Drepanididæ in the Hawaiian group[7].

SECONDARY SEXUAL PLUMAGE

In Geospiza species the adult male plumage is black, but individuals frequently breed in the grey-brown juvenal plumage, or in partly black and partly juvenal plumage. In Platyspiza and Camarhynchus, the 'full' male plumage is partly black, and many individuals breed in juvenal plumage, the percentage greatly varying on different islands. In Cactospiza, the male is normally coloured like the juvenal, but one had a black head. This tendency to lose the male secondary sexual plumage occurs in many other land birds of oceanic islands. Such plumage is usually considered to have evolved through purely intra-specific selection, through threat and courtship display, and one would suppose threat and courtship were as essential on oceanic islands as elsewhere (Geospizinæ display vigorously). But there is a further function of such plumage which has relation to other species, namely, enabling the female to recognize and pair up with a male of her own species, hybridization being at a selective disadvantage. The few land birds which have colonized oceanic islands are normally removed from all related species which the female might possibly confuse with her own, so this function disappears. The opposite of this process is seen in some continental Gallinaceous birds, and some birds of paradise, in which the sexes meet only for copulation and there is not the complex inter-related pairing behaviour typical of birds in which both sexes raise the young. Probably correlated with this, hybridization is relatively common, and at the same time there is an extreme development of male secondary sexual plumage, each species being strikingly distinct.
